INDICATIONS AND CONTRAINDICATIONS FOR MEDULLARY NAILING OF FRACTURES

J. Albert Key, M.D., St. Louis

American surgeons have now had sufficient experi- ice with medullary fixation to permit them to accept this ethod as a valuable addition to our armamentarium in e treatment of fractures of long bones. However, the in- oduction of a suitable nail may require an operative posure of the fracture site, and this converts a simple acture into a compound one with its attendant danger of fection and of nonunion. Furthermore, the danger of fection seems to be greater after medullary nailing than ter most other clean surgical operations. Consequently, ie method should not be used routinely and fractures iat can be treated satisfactorily by closed reduction and cternal fixation, or by traction, should be so treated. The equency with which medullary fixation is used will and iould vary directly with the surgeon's interest and skill i the use of the method and indirectly with his ability) treat fractures by more conservative measures.

The insertion of a medullary nail is usually a relatively mple procedure, but at times it may entail a very dif- cult operation that is fraught with danger to the patient. onsequently, it should not be tried by the uninitiated. prerequisite for the insertion of such a nail is the pres- nce of a surgeon who has had experience with the ethod and is available to perform the operation. It is lso necessary that the proper nails for this particular one be on hand and that the operation set contain in- truments for inserting and extracting the nail. These hould include a long drill and broach or reamer for en- rging the canal if necessary and a hacksaw or large bolt utter for cutting the nail off in case it should become im- acted and the surgeon not be able to remove it without nduly shocking the patient.

INDICATIONS FOR MEDULLARY NAILING

Bones Most Suitable for Nailing.—The bones most uitable for nailing are the long bones. In my opinion the elative frequency with this procedure as indicated in ractures of various bones is: femur, phalanges of fingers, ibia, metacarpals, radius and ulna, humerus, fibula, and metatarsals. The femur is ranked first because of the difficulties in treating fractures of the shaft of this bone by more conservative methods and of the shortening of the period of hospitalization and of disability that result from a successful nailing of a fracture of the shaft of the femur.

The fingers are ranked second because fixation with a Kirschner wire may not only preserve function in the fractured finger but permits the use of the rest of the hand while the fracture is healing and tends to prevent the stiffness that too often follows prolonged immobilization of this member. The tibia is ranked third because Lottes [1] has shown that closed reduction and blind nailing of this bone is a practical procedure and because results are better than those obtained by other methods (Lottes and Key [2]). The humerus is put low in the scale because most fractures of this bone can be treated successfully by much simpler methods, for instance, the hanging cast. The reasons for the order in which the other bones are ranked should be apparent to anyone who treats many fractures, but opinion may vary as to the relative frequency with which nailing is indicated in fractures of the various bones. However, the nail should be reserved for those fractures where it presents a definite advantage over the results obtained by more conservative methods or where circumstances justify the added risk in order to shorten the periods of hospitalization and disability.

Type of Fracture.—It is generally agreed that the ideal fracture for nailing is a simple transverse or short oblique fracture in the middle third of a long bone. To this should be added double and triple fractures of the shaft of a long bone, because of the difficulties in treating these by closed reduction or traction and the tendency of one or more of the fractures not to unite when treated conservatively or by open reduction and plating. However, with increased experience surgeons are now finding that fractures within 3 in. (7.6 cm.) of either end of the femur or tibia can be nailed successfully in the conventional manner if the nail is supplemented by external fixation. This is especially

true of the tibia, because here we routinely apply a walking cast that is to be worn until the fragments are united. Also, with the use of two slightly curved Rush nails it is possible to fix supracondylar fractures of the femur or humerus quite firmly, and this may be supplemented by external fixation if necessary. Likewise, fractures of the proximal portion of the humerus can be stabilized with a nail or wires driven down through the greater tuberosity and into the shaft. This is especially indicated in fracture-dislocations of the shoulder.

Vom Saal[3] has used Kirschner wires to fix fractures near and including the ends of the metacarpals and phalanges, and Rush and Rush[4] have used a Rush nail through the major fragment and down the medullary canal of the radius in the treatment of severe Colles' fractures. Some surgeons are successful in using a medullary nail in the treatment of long oblique fractures and of comminuted fractures, especially of the butterfly type. But in these it may be necessary to reinforce the nail with one or more screws or encircling wires or bands, just as it may be advisable to bridge the fracture of a femur with a bone plate in instances where the nail does not fit tightly enough to prevent rotation deformity. This fixation in rotation is one of the reasons why it is advisable, especially in the femur, to use the largest nail that the bone will accommodate. Also the surgeon should supplement the nail with external fixation where there is any doubt as to the efficiency of the fixation by the nail.

Whether compound fractures may be nailed either immediately at the time of débridement or later after the wound has healed is a moot question. The insertion and leaving of the large foreign body in the bone undoubtedly interferes with the blood supply of the bone and increases the trauma to soft tissues and thus adds to the danger of infection. Consequently, many surgeons feel that the nail should not be inserted at the time of the débridement and primary suture. Others, however, believe that the more perfect immobilization produced by the nail more than balances the added danger of infection and insert the nail at the time of the débridement. When the nail is inserted at the time of the débridement, the wound may be closed, drained, or packed open. The presence of the nail does not appreciably affect the treatment of the wound except that it affords fixation of the fragments and thus tends to facilitate care of an open wound and lessen the spread of infection.

If so much time has elapsed since the injury that the wound cannot be closed by primary suture with relative safety, it is unwise to insert the nail at this time and the wound should be left open and the fracture treated by traction or a cast. The time of relative safety for primary suture is from 6 to 12 hours, depending upon the severity of the damage to the soft tissues and of the contamination of the wound and whether the patient has had adequate antibiotic therapy. When the wound is closed by delayed primary or secondary suture a medullary nail may be inserted only if the wound is unusually clean; otherwise one should wait until the wound is healed and then insert the nail. If it can be done without exposing the fracture, the nail may be inserted in about two weeks, and when this is done the skin sutures should not be removed until after the nail is in place.

Ordinarily the presence of infection at the fracture site is a contraindication for medullary nailing. However, in selected cases it is a very valuable method even in the presence of infection and may obviate prolonged immobilization in bed, with sepsis, cachexia, kidney stones, and eventual nonunion. Brav and Jeffress[5] have reported 8 such cases of old, infected gunshot fractures of the femur, and Lottes has nailed 12 chronically infected fractures with nonunion (each with a high percentage of successes). At the operation the wound is carefully débrided, the ends of the bone are freshened, and the nail is then inserted in the ordinary manner. The wound is left wide open, preferably with posterior drainage, the extremity is immobilized in a splint or a plaster cast, and antibiotic treatment is given. There appears to be little danger of spreading the infection down into the distal fragment.

In pathological fractures of long bones medullary nailing may be the best form of treatment available because it shortens the convalescence and relieves the pain in patients who may not have very long to live and to whom each day of normal activity is important. Here, too, there appears to be little danger of the nail spreading the tumor down the medullary canal. In selected impending pathological fractures it is good practice to insert a medullary nail before the fracture occurs. In fractures of long bones with delayed union or nonunion, a medullary nail is an excellent type of internal fixation, as it tends to immobilize the ends of the fragments and permits impaction and partial weight bearing. If the bone ends are sclerotic it may be necessary to ream out the medullary canal in order to permit passage of the nail. When the site of the nonunion is exposed for nailing and after the nail is in place, one or more grafts of autogenous compact or cancellous bone are placed across the fracture site and the soft tissues are sutured over them. No grafts are used if there is evidence of infection at the fracture site. In the leg or forearm it may be advisable to resect a section of or obliquely osteotomize the intact bone in order to permit approximation and impaction of the bone ends. Some surgeons advise the routine insertion of bank or autogenous bone grafts when a fresh fracture has been nailed by open operation, but this has not been our practice.

CONTRAINDICATIONS FOR MEDULLARY NAILING

Fortunately, the contraindications for medullary nailing are not as numerous as the indications. They may be divided into general and local: The first general contraindication, as stated above, is the lack of the necessary equipment and skilled personnel. The second is the condition of the patient. It is unwise to subject a patient in shock or impending shock to a major elective operation, and the insertion of a medullary nail is an elective procedure. It is better to immobilize the fracture by traction or in a plaster cast or splint and operate on the fracture later after the general condition of the patient has improved. Likewise, in a case of multiple fractures where such treatment is indicated for two of more fractures, it may be advisable to nail one and then do the others a few days later. This will depend upon how smoothly the first op-

eration goes and how well the patient is doing when it is finished. On the other hand, in a patient who is in poor general condition after long conservative treatment in bed for a fracture of the femur it may not be possible to get him in good condition before the operation. In such cases the fixation of the fracture with a medullary nail may be a lifesaving measure and while risky is justified even in the presence of pressure sores. With careful preparation of the skin and draping of the patient, it is possible to exclude such areas from the operative field and by the preoperative and postoperative use of antibiotics to lessen the danger of infection.

Infection in or near the fracture site is usually a contraindication, but, as mentioned above, there are exceptions to this rule. Poor condition of the skin over the operative field is a danger that may be overlooked. This is especially apt to be present after prolonged immobilization in a plaster cast. I have seen one case of postoperative infection after nailing of the femur that I attributed to this cause. A longer time should have been allowed after the removal of the cast and until it was possible to get the skin over the operative field into good condition. Also in reopening a recent wound that has been closed after débridement of a compound fracture or after open reduction and internal fixation of a simple fracture the surgeon should look for evidence of a low-grade infection and take cultures from the depth of the wound. In such cases, even when no evidence of infection is found, it is advisable to place a small drain in the wound and remove it after 48 hours if all seems to be going well or to open the wound widely if there is evidence of infection. I have seen one such infection of a tibia that had been fixed with a metal plate two weeks previously. As the fragments were maintained in slight distraction I decided to remove the plate and insert a medullary nail. No evidence of infection was seen at the operation, but in spite of postoperative antibiotic therapy an infection occurred, and it was only after several months of drainage and a third operation that union and final healing of the wound were secured. The possibility of inserting a nail in the presence of chronic infection has been considered above.

Age of the patient may also be considered a contraindication, because, while in patients of advanced age I am inclined to nail a femur or a tibia in order to shorten the disability, I do not nail such fractures in children. This is because I am afraid that the passage of the large nail through the epiphysial line might disturb the growth of the bone and also because such fractures can usually be treated satisfactorily by conservative means. I have nailed these bones in adolescents with excellent results and have not seen any disturbance in growth caused by the nail.

A further contraindication is the site and character of the fracture, as discussed above. However, with increased experience and the use of supplemental internal and external fixation I am now finding the nail useful in selected long oblique and comminuted fractures and in those near the ends of the bone. An objection, but not a contraindication for nailing, is that removal of the nail after the fracture has united is usually advisable. This may require a second hospitalization and operation. In many cases, however, the patients do not return for removal of the nail, and it seems probable that many of these nails may remain in situ indefinitely and cause no symptoms.

SUMMARY

While medullary nailing of fractures is a valuable addition to our fracture armamentarium, it is a radical procedure, and usually the proper insertion of such a nail requires an open reduction of the fracture and special equipment. Consequently, it is not recommended for routine use, and fractures that can be treated satisfactorily by more conservative methods should be so treated. The operation may be difficult and should not be undertaken by the uninitiated but reserved for the expert fracture surgeon who is working in a well-equipped hospital. And even he should fit his treatment to the fracture and the patient rather than nail every fracture that can be nailed. Additional fixation in a cast or splint should be used in cases where the nail does not effect sufficient immobilization of the fragments.

Fixation by medullary nailing is especially indicated in simple transverse or short oblique fractures of the middle third of the femur, phalanges, tibia, and forearm bones. In experienced hands the method may be used in fractures nearer the ends of long bones and in long oblique, comminuted, and compound fractures. It is contraindicated in children, in patients in shock, in areas of infection, and in fractures in which an intramedullary nail is not mechanically efficient in immobilizing the fragments.

700 S. Kingshighway.

Pernicious Anemia.—At the present time many dozens of proprietary preparations contain both folic acid and vitamin B_{12}, usually in addition to other vitamins and iron. These preparations, although often advertised to be good for "all anemias" are not satisfactory for treatment of pernicious anemia. The vitamin B_{12} contained in these oral preparations is not absorbed and is therefore ineffective. Folic acid, on the other hand, is readily absorbed and may produce a hematologic remission while allowing neurologic symptoms to develop or progress. Many of the currently available multivitamin preparations contain sufficient folic acid to correct completely the blood and marrow abnormalities of patients with pernicious anemia.

The early symptoms of pernicious anemia include fatigue, weakness, soreness of the tongue, mild gastrointestinal disturbances and numbness and tingling of the hands and feet. A patient who develops one or the other of these symptoms is very likely to receive a multivitamin preparation, without appreciation of the correct diagnosis. If the preparation contains folic acid, anemia disappears before it was recognized to be present, alimentary symptoms subside and the patient often feels much improved. Weeks or months later, however, progressive neurologic disease will become apparent and may incapacitate the patient while the blood remains normal. At this time the physician often does not think of pernicious anemia, but considers the diagnosis of multiple sclerosis, cord tumor or some other neurologic disease. Since the diagnosis is not recognized, the patient may be deprived of the simple therapy which could have maintained him in excellent health.

Since the use of folic acid has become widespread, almost half of the new patients with pernicious anemia seen at the Johns Hopkins Hospital arrive with neurologic disease in the absence of an appreciable degree of anemia. Folic acid deficiency is extremely rare in the United States, and the indiscriminate use of this vitamin is not justified. Under no circumstances should folic acid in any form be administered to a patient whose symptoms might be those of pernicious anemia.—C. Lockard Conley, M.D., Pitfalls in the Diagnosis of Pernicious Anemia, *GP,* January, 1955.

PRACTICAL SCHEME FOR FLUID AND ELECTROLYTE THERAPY IN CHILDREN

C. Harrison Snyder, M.D., New Orleans

The purpose of the present paper is to outline in simple, concise form a practical routine for prescribing fluids for parenteral use in pediatric patients. The vast new literature on fluid and electrolyte therapy, stressing the role of potassium, has upset older concepts, which emphasized sodium therapy and acid-base balance, and the result for many busy practitioners has been a certain amount of uncertainty and confusion. At the request of surgeons and pediatricians alike, I have endeavored to draw up a few simple rules for therapy based on the fundamental research of Darrow, Butler, and many others. These rules and principles, which will be outlined later, have been in use in our clinic now for over one year and have proved not only simple and practical but also adaptable to nearly all surgical and medical situations that call for the parenteral use of fluids. First of all, in prescribing the fluid needed by any patient during a 24 hour period, we like to take into account three basic requirements: (1) the daily maintenance requirement; (2) fluids required to compensate for current abnormal losses (e. g., diarrhea, vomiting, and gastric suction); and (3) fluids needed to correct preexisting deficits. Each of these will be discussed in turn.

DAILY MAINTENANCE REQUIREMENTS

Butler [1] has shown that the daily requirements of water, sodium, and potassium in childhood are a function not of age or body weight but more exactly of body surface area. For this reason, in each case we calculate the surface area of the patient, which can be derived from his height and weight by using the familar nomogram of DuBois (contained in the standard pediatric texts of Holt-McIntosh and Mitchell-Nelson, and also available commercially in convenient printed sheets.) From Butler's figures we derive the following daily maintenance requirements per square meter of body surface:

Water	Na	K
1,500 Cc.	30 mEq.	20 mEq.

Thus, a 2-year-old patient with a height of 80 cm. and weight 12 kg. has a surface area of 0.5 square meters and would need daily 750 cc. of water (or sugar solution) containing 15 mEq. of sodium chloride and 10 mEq. of potassium chloride.

We prefer 10% invert sugar as the source of water and calories since it provides more calories than does 5% glucose and obviates the risk of glycosuria so common when 10% glucose solution is used. As the source of sodium chloride we use a special solution containing 17.4 gm. of sodium chloride in 100 cc. of distilled water. This is 3 M sodium chloride and contains 3 mEq. of sodium chloride per cubic centimeter. A similar 3 M solution of potassium chloride that contains 22.3 gm. of potassium chloride per 100 cc. provides 3 mEq. of potassium chloride per cubic centimeter. It, too, is made up in our own hospital, but one could as well use the commercially available molar solutions of sodium and potassium chloride. Thus in the case of the 2-year-old child who has been already described, one might make up the day's fluid as follows: from 1 liter of 10% invert sugar discard 250 cc.; to the remainder add 5 cc. of 3 M sodium chloride and 3.3 cc. of 3 M potassium chloride. Such a mixture contains 15 mEq. of sodium chloride and 10 mEq. of potassium chloride in 750 cc. of water and fulfills the daily maintenance needs. It should drip at such a rate as to require 24 hours for its absorption.

It is noteworthy that by adding the potassium to the entire day's fluid volume one avoids the danger of suddenly "flooding" the patient with too much potassium, as might occur if potassium were given in a separate bottle over a brief period. Another practical point is that patients can tolerate large volumes of water, even twice the basal requirements,[2] provided the salt content is not excessive. For this reason, we might be inclined to use a full liter of sugar solution in the above case instead of only 750 cc. By so doing more calories would be offered without danger of edema. In point of fact, we feel that patients with fever may well require more than 1,500 cc. per square meter per day and lately have tended to give 2,000 cc. per square meter per day for febrile patients and for surgical patients in the first day or two following operation.

REPLACEMENT OF ABNORMAL LOSSES

Whenever there are abnormal losses through diarrhea, vomiting, gastric suction, or spinal fluid leakage, etc., such losses are measured or carefully estimated. On the following day these losses are replaced by appropriate amounts of water, sodium chloride, and potassium chloride given in addition to the daily maintenance requirements. Gastric, intestinal, and biliary juices vary considerably in their composition but are all essentially isotonic with plasma, containing about 150 mEq. of electrolyte per liter.[3] Their potassium content varies from 5 to 20 mEq. per liter. The rest of the cation content is mostly sodium, except in the case of gastric juice, which is high in hydrogen ion.

For practical purposes for each liter of such fluid loss we replace 1,000 cc. of water, 135 mEq. of sodium chloride, and 15 mEq. of potassium chloride. Thus, in the case of the 2-year-old child weighing 12 kg. and having a surface area of 0.5 square meters, if we find the child has lost 200 cc. of diarrheal stool, we will give on the following day 200 cc. of water (as sugar solution), 27 mEq. of sodium chloride and 3 mEq. of potassium chlo-

ride in addition to the daily maintenance needs. More exactly we would prescribe as follows:

Purpose	Water, Cc.	Sodium, mEq.	Potassium, mEq.
Maintenance	750	15	10
Replacement of current losses through diarrhea	200	27	3
Total	950	42	13

The figure 950 could be rounded off to 1,000 cc., so that in practice we would take 1,000 cc. of 10% invert sugar, add 14 cc. of 3 M sodium chloride and 4.3 cc. of 3 M potassium chloride. This volume should drip slowly over 24 hours.

CORRECTION OF PREEXISTING DEFICITS

The matter is somewhat more complicated in patients admitted in a state of dehydration and acidosis, as for example in infants with diarrhea, in diabetic coma, or in patients with intestinal obstruction or peritonitis. Such patients may have great deficits of water, sodium, and potassium that have to be met. They also have disturbances of pH, but as Darrow and Pratt[4] pointed out acidosis per se is usually of secondary importance, and our first efforts must be to combat shock, restore blood volume, and replace electrolytes. Once this is done the kidneys can nearly always be trusted to adjust the pH of the blood. We no longer depend on determinations of serum bicarbonate to guide us in administering alkali and in fact usually proceed with therapy without drawing blood for this determination.

As stated, in dehydration our first effort is to overcome shock and restore blood volume. For this purpose we use an "initial mix" after the manner of Butler. This initial mix is a solution essentially similar to extracellular fluid but only half isotonic as regards electrolyte. It contains 75 mEq. per liter of sodium, 50 mEq. per liter of chloride, and 25 mEq. per liter of lactate. To prepare the solution we take 1 liter of 5% glucose and add 50 mEq. of sodium chloride (17 cc. of our 3 M sodium chloride) plus 25 mEq. of sodium lactate (we use molar sodium lactate available in ampuls made by Abbott Laboratories, and we add 25 cc. of this to the liter of 5% glucose). The solution is given rapidly over a period of about two to three hours until the patient begins to urinate. As a rule we give 30 cc. per kilogram; then if the patient has voided we discontinue the initial mix. After this we may give a blood transfusion of about 320 cc. per square meter of body surface, if the patient seems to be in shock. In less severe cases the blood is omitted. Next, having reestablished renal function, we must calculate the fluid requirements for the rest of the day.

Butler[1] has shown that in dehydration fluid is lost from both the extracellular and the intracellular compartments, and his balance studies indicate that about half the loss is extracellular fluid and half is intracellular fluid. Extracellular fluid contains much sodium, roughly 150 mEq. per liter, but little or no potassium. Intracellular fluid, on the contrary, contains nearly 150 mEq. per liter of potassium but little or no sodium. In severely dehydrated infants 10% of the body weight may be lost; that is, roughly 100 cc. of fluid is lost for every kilogram of body weight. Of this 100 cc., 50 cc. is extracellular and would contain 7.5 mEq. of sodium, and 50 cc. is intracellular and would contain 7.5 mEq. of potassium. Thus, Butler derived the rule that, with 10% of the body weight lost through dehydration, there is a loss, per kilogram of body weight, of 100 cc. of water, 7.5 mEq. of sodium, and 7.5 mEq. of potassium, which will have to be replaced. However, some of this loss (particularly the *intracellular portion*) represents actual breakdown of protoplasm and cannot be replaced until food is taken and new protoplasm is formed. Thus, for purposes of immediate fluid replacement, our rule is that in cases of 10% dehydration one should replace, per kilogram of body weight, only 80 cc. of water, 6 mEq. of sodium, and 4 mEq. of potassium. Unfortunately, we have no method other than clinical judgment for estimating the amount of weight lost by the patient before he comes to us. In practice, if dehydration seems severe, we assume 10% weight loss and proceed to replace water, sodium, and potassium in the quantities mentioned. In milder states we may assume only 5% dehydration and give half the quantities recommended.

To proceed with our example, if our 2-year-old child, weighing 12 kg., with a surface area of 0.5 square meters, is admitted with diarrhea and severely dehydrated, we would use the rule of giving, per kilogram, 80 cc. of water, 6 mEq. of sodium, and 4 mEq. of potassium, and our figures for this 12 kg. child would be, for correction of dehydration, water, 960 cc.; sodium, 72 mEq.; and potassium, 48 mEq. To this we add the daily maintenance requirements based on a surface area of 0.5 square meters: water, 750 cc.; sodium, 15 mEq.; and potassium, 10 mEq. We thus arrive at a total of: water, 1,710; sodium, 87 mEq.; and potassium, 58 mEq.

At this point we must recall that we have already administered a certain volume of initial mix, namely, 30 cc. per kilogram, or in this case 360 cc. This initial mix contains, per liter, 75 mEq. of sodium, so that we have given 360 cc. of water containing 27 mEq. of sodium, and these figures must be subtracted from the total daily needs. The adjusted figure is then: water, 1,350; sodium, 60 mEq.; and potassium, 58 mEq. The figure 1,350 could be rounded off to 1,500, and so to prepare this solution one might take 1,500 cc. of 10% invert sugar, add 20 cc. of 3 M sodium chloride and 19 cc. of 3 M potassium chloride. In practice, however, since sugar solutions come in 500 cc. and 1,000 cc. sizes, we would use 1 liter of 10% invert sugar, to which we would add two-thirds of the electrolyte, this to be followed by a half-liter bottle containing one-third of the electrolyte, and all to run in over 24 hours.

This method of figuring, although perhaps appearing complicated at first, becomes remarkably simple with practice, has the virtue of being based on sound physiological principles, and has given us gratifying clinical results. A special advantage of this method of prescribing is that for each patient a mixture is prepared that is suited to his own needs, and this mixture is designed to provide for all his needs for a full 24 hour period. Other methods of therapy, which utilize ready-made sodium and potassium mixtures, are less easy to adapt to the needs of the individual patient and often involve changing solutions several times during the day. The objection may be raised that our extemporaneously prepared mixtures are always hypertonic, containing 10% sugar with added salt. This is true; yet in practice we have had no more difficulty with thrombophlebitis than we have seen with use of isotonic fluid.

---

[4] Darrow, D. C., and Pratt, E. L.: Diarrhea, in Pediatrics, ed. 12, New York, Holt & McIntosh, 1953, p. 247.

PRECAUTIONS TO BE OBSERVED

The dangers of hyperpotassemia are well known. For this reason in giving potassium certain precautions must be observed. First, we withhold potassium until we are sure that the patient is voiding. Secondly, the daily allowance of potassium is made to run in slowly over the entire 24 hour period. In case the infusion stops and time is lost, we may have to speed up the rate of flow toward the end of the day, but in no case is the total daily allowance of potassium permitted to be absorbed in less than six hours. Finally, we withhold or postpone potassium therapy in patients with clinical evidence of disease known to predispose to hyperpotassemia. Such conditions are nephritis, lower nephron nephrosis, severe burns, extensive crushing injuries, and adrenocortical failure. With the foregoing exceptions, it will be found that patients tolerate large amounts of potassium provided it is given slowly and continuously over a 24 hour period. Butler [5] has found that the normal adult can tolerate up to 225 mEq. of potassium per square meter of body surface per day. Only in the exceptional cases such as those mentioned do we find it necessary to utilize the electrocardiogram or the flame photometer to detect evidence of excessive circulating potassium.

Certain special conditions may require modification of the routine outlined. One such is dehydration due to vomiting (as in pyloric stenosis), where alkalosis may be present. Here, in treating the dehydration our initial mix is better made without sodium lactate. Instead we use half-normal saline; that is, 1 liter of 5% glucose to which is added 75 mEq. of sodium chloride. Except for this modification our routine in alkalosis is the same as in dehydration with acidosis. Patients with severe burns constitute another special problem to which the present routine would not apply. Currently, we are using the program of fluid therapy outlined by Evans [6] for the management of severe burns. Patients with renal failure, as in so-called lower nephron nephrosis, also present a special problem, which is beyond the scope of the present paper.

In general, we believe that all patients maintained on parenterally administered fluid more than four or five days deserve special supervision. In these cases, although we continue to follow the outline of therapy presented, we prefer to check our therapy by determinations of serum chloride and bicarbonate levels every two or three days. We watch particularly for depression of serum chloride and elevation of serum bicarbonate level (hypochloremic alkalosis). Such signs would indicate hypopotassemia and the need for additional potassium therapy. In patients receiving prolonged intravenous therapy we also test the urine daily for acetone (since it is virtually impossible to provide adequate calories by the intravenous route) and for chloride, by the simple bedside quantitative test of Fantus.[7] If the urinary chloride level is less than 1 gm. per liter, we give additional sodium chloride.

Although these precautions need to be observed, it is noteworthy that, in the vast majority of our patients who have no renal disease and in whom therapy is continued only two to four days, we have simply adhered to the rules of therapy as outlined and have not found it necessary or even helpful to measure serum electrolyte levels. Dehydration, acidosis, and deficiencies of sodium, potassium, and chloride have corrected themselves promptly without clinical evidence of any inaccuracies in therapy.

It should be noted that everything already discussed refers to intravenous therapy only. It is our feeling that any patient who deserves parenteral therapy deserves intravenous therapy. The subcutaneous route does not permit the prescription of ideal mixtures of sugar and electrolyte or the proper control of their rates of absorption. With modern equipment, including special scalp vein needles,[8] one seldom has to resort to surgery to get a needle into a vein and hardly ever needs to be content with any less effective route for parenteral therapy. It might be added that the principles outlined here can perfectly well apply, without change, to adult patients as well as to children.

SUMMARY

For the conduct of intravenous fluid and electrolyte therapy in medical and surgical patients of the pediatric age group, we employ only five different solutions, i. e., 5% glucose, 10% invert sugar, 3 M sodium chloride, 3 M potassium chloride, and 1 M sodium lactate. For each patient, once each day, a proper mixture of these solutions is prepared to provide for all his needs for a 24 hour period. In prescribing these fluids we give the following amounts of fluid: (1) for daily maintenance, per square meter of body surface, 1,500 cc. of water, 30 mEq. of sodium chloride, and 20 mEq. of potassium chloride; (2) for replacement of current abnormal losses (diarrhea, vomiting, gastric suction, etc.), per liter of such fluid lost, 1,000 cc. of water, 135 mEq. of sodium chloride, and 15 mEq. of potassium chloride; (3) for correction of dehydration, assuming 10% weight loss through dehydration, per kilogram of body weight, 80 cc. of water, 6 mEq. of sodium chloride, and 4 mEq. of potassium chloride (for moderate dehydration, only half these quantities); and (4) for beginning therapy of dehydrated patients, a potassium free "initial mix" containing, per liter, 50 mEq. of sodium chloride and 25 mEq. of sodium lactate. Potassium is given only after renal function has been reestablished. Certain precautions must be observed in the application of these rules, particularly in regard to the dangers of potassium therapy.

SURGICAL TREATMENT OF BRONCHIECTASIS IN CHILDREN

Jack C. Cooley, M.D., Robert L. Ginsberg, M.D., Arthur M. Olsen, M.D., John W. Kirklin, M.D.
and
O. Theron Clagett, M.D., Rochester, Minn.

A previous study[1] summarized the over-all results in a series of 221 patients of all ages who underwent surgical resection for bronchiectasis. The present study represents an evaluation of the 30 children, ranging in age from 5 to 14 years, included in that series. Fourteen of the patients were boys, and 16 were girls. Pulmonary resection was carried out in all instances, with the patient under general endotracheal anesthesia; a posterolateral incision was used, with individual ligation of hilar structures. All patients were operated on prior to December, 1952, and all were followed by direct observation of the child and by follow-up letter. Preoperative bronchoscopy was done in all cases, as were bronchograms. Pathological examination confirmed the clinical impression in all cases.

CLINICAL RESULTS

The clinical results in this series of 30 cases were good in 18 (60%), fair in 7 (23.3%), and poor in 4 (13.3%). No operative deaths occurred, but one patient died several months after operation as the result of progressive sepsis. A good result was one in which the patient was returned to full activity and had few or no remaining symptoms. A fair result indicated that some limitation of activity was present but that the residual symptoms were not incapacitating. A poor result designated either little improvement or worsening after operation. These results compared unfavorably with those obtained in the aforementioned series of 221 patients of all ages, in whom good results were noted in 75%, fair results in 16%, and poor results in 5%. The remaining 4% represented deaths. Bilateral resection was not done in this series of children. Two pneumonectomies were carried out. The remaining patients underwent unilateral resection. Table 1 summarizes the extent of pulmonary resection and the respective results.

COMPLICATIONS

The postoperative complications encountered were retention of secretion, pleural effusion requiring thoracentesis, bronchopleural fistula, and pneumothorax. Table 2 outlines the incidence of these complications. This presents a striking contrast to the incidence of complications seen in the series of patients of all ages, in which they occurred less than half as frequently. Retention of secretion requiring postoperative bronchoscopy occurred in 60% of these children. This is to be compared with an incidence of 25.8% in the larger series of 221 patients. We consider that this increase in postoperative retention of secretion in children is directly related to their failure to cough sufficiently after thoracotomy. Since this study, therefore, we have liberalized the indications for doing concomitant tracheotomy at the time of thoracotomy in order to mitigate retention of secretion and help prevent the bronchoscopy that such retention necessitates. It is our impression that the more frequent use of concomitant tracheotomy will serve to improve the postoperative course of these children and thereby enhance the possibility of good results.

TABLE 1.—*Extent of Operation Related to Results*

	Results			
Extent of Resection	Good	Fair	Poor	Dead (Late)
Pneumonectomy	1	0	0	1
Unilateral, 1 lobe	7	3	1	..
Unilateral, 2 lobes	10	4	3	..

TABLE 2.—*Complications of Pulmonary Resection in Thirty Cases*

	Cases	
Complication	No.	%
Retention of secretion	18	60.0
Pleural effusion	3	10.0
Bronchopleural fistula	2	6.6
Pneumothorax	1	3.3

NEW BRONCHIECTASIS

Documented new bronchiectasis was found after operation in 5 of the 30 children (16.6%). This is doubtlessly a minimal figure, since postoperative bronchograms were done on only 13 patients. In addition, two patients had proved progression of residual disease. Unsatisfactory results were observed in all of these seven patients with new or progressive bronchiectasis. As compared with the previously mentioned study, this shows increased tendency toward formation of new and progressive bronchiectasis in children and further explains the poorer results in their treatment by pulmonary resection.

RESIDUAL BRONCHIECTASIS

All pulmonary tissue involved with bronchiectasis was resected in 16 of the 30 patients in this series; 11 (69%) of this group obtained good results. The remaining 14 patients manifested some residual disease; 7 (50%) of this group obtained good results. Only one of three patients with ipsilateral residual disease had good results. We believe these figures, though small in number, show a trend associating residual disease with poorer results.

COMMENT

It was disappointing to find that the results after surgical treatment of bronchiectasis in children were not so good as the results in a series that included patients of all age groups. Certain factors appear to be implicated. A definite increase in the incidence of postoperative complications, particularly retention of secretion, was noted in children. These young patients also showed an increased tendency for postoperative development of new bronchiectasis, a particularly serious complication in children. It appears to us that the afore-mentioned factors play an important role in determining the results of surgical treatment of bronchiectasis in children. Also, possibly incomplete development or increased susceptibility to infection contribute to the different results obtained in treatment of this disease in children and adults.

were all relieved at variable intervals after administration of glyceryl trinitrate. On one occasion, the blood specimen obtained about an hour after the attack of angina (four hours after meal) showed a drop in the plasma lactescence level.

The solid line in figure 2 represents a curve of the average plasma lactescence values following test meals in the 13 remaining patients with severe coronary artery disease and angina pectoris. This curve shows a gradual rise of the turbidity level to its peak about five hours after fat ingestion, which is considerably later than that of the patient with hyperlipemia presented in figure 1. Without exception, the individual plasma lactescence curves of these 13 patients follow the composite curve very closely. Interestingly enough, each of the 10 attacks of angina pectoris observed in this group of patients was found to occur about four and one-half to five hours after the fat meal, while plasma lactescence was at or near its peak value.

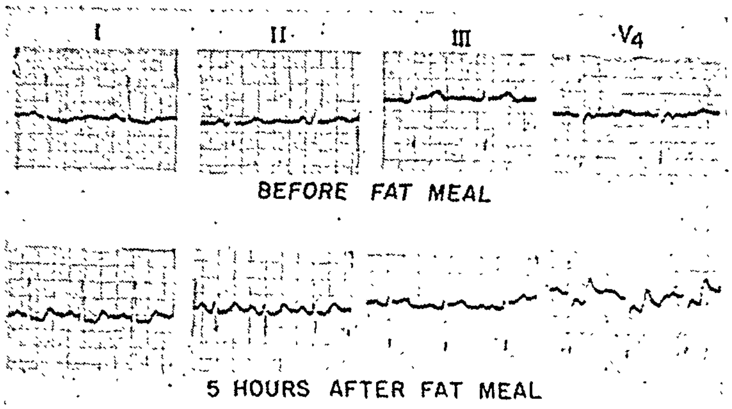

Fig. 3.—Electrocardiograms obtained in patient with coronary artery disease before and after fat meal. The lower tracing was taken while the patient was having anginal pain.

The dotted line in figure 2 is a curve of the average plasma turbidity values, following the ingestion of nonfat meals, obtained from three of the six patients who had previously developed anginal pain with a fatty meal. The curve is low and remains essentially flat throughout the period of study. No anginal pain was elicited in any of the three patients after the ingestion of the nonfat meal.

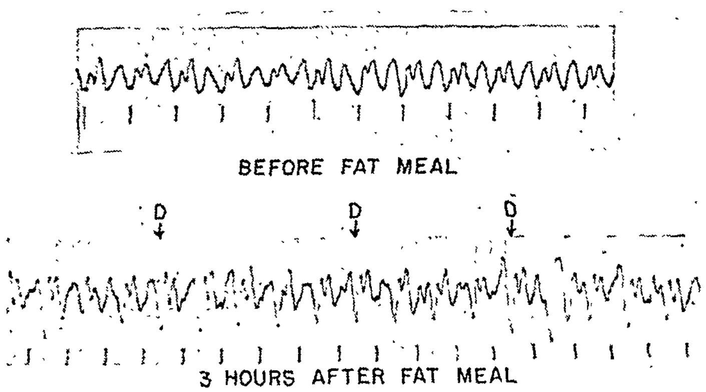

Fig. 4.—Ballistocardiograms obtained from patient with idiopathic hyperlipemia and coronary artery disease. "D" in the lower tracing indicates the appearance of a larger V-shaped early diastolic wave with the onset of angina pectoris. Markers denote R waves in electrocardiogram.

Effects of Fat Meal on Electrocardiogram.—The control electrocardiograms of all except one of this series of patients were abnormal. None of the patients showed a significant change in the electrocardiogram sooner than three hours after the meal. With the onset of angina pectoris, three to five hours after fat ingestion, definite changes in the electrocardiogram were noted in four of these patients. These changes were transitory, disappearing promptly with the subsidence of anginal pain. An increase in cardiac rate, an increased depression of the already depressed RS-T segment of more than 0.50 mm., and a shift in the amplitude of the T waves were found in three of these four patients. A lowering of the amplitude of the T waves was recorded in two patients together with the RS-T segment depression. The T wave in a 54-year-old female with hypertension and severe coronary artery disease became more upright in the limb and chest leads, while the RS-T segment was markedly depressed during the attack. Her control and five-hour postprandial tracings are shown in figure 3. The remaining patient showing electrocardiographic changes developed frequent ventricular extrasystoles soon after the onset of chest pain four and one-half hours after the meal but showed no distinct alteration in the RS-T segments in the electrocardiogram.

Effect of Fat Meal on Ballistocardiogram.—Twelve of the 14 patients in this series have very abnormal ballistocardiograms. No distinct change from the control tracing could be detected in any of the patients before the onset of anginal pain, three to five hours after the ingestion of a fat meal. In six patients, extremely marked changes in the ballistocardiogram were observed during each of the 14 attacks of angina thought to be precipitated by the fat meal; of these patients, evidence of gallbladder disease was found in only one. The abnormal ballistic changes were found to persist the duration of the anginal attack; the record would gradually return to the control pattern 10 to 15 minutes after the patient was free of pain. Figure 4 shows ballistocardiograms of a patient with hyperlipemia, coronary artery disease, and congestive failure made before and three hours after the fat meal with the development of angina. The control ballistocardiogram before the fat meal is markedly abnormal, with a short I wave, wide and notched J wave, and prominent diastolic waves. The tracing taken immediately after the appearance of chest pain, three hours after the fat meal, shows a completely different ballistocardiographic pattern. Besides the prominent respiratory variations, the amplitudes of the diastolic waves (D) are greatly exaggerated and in-

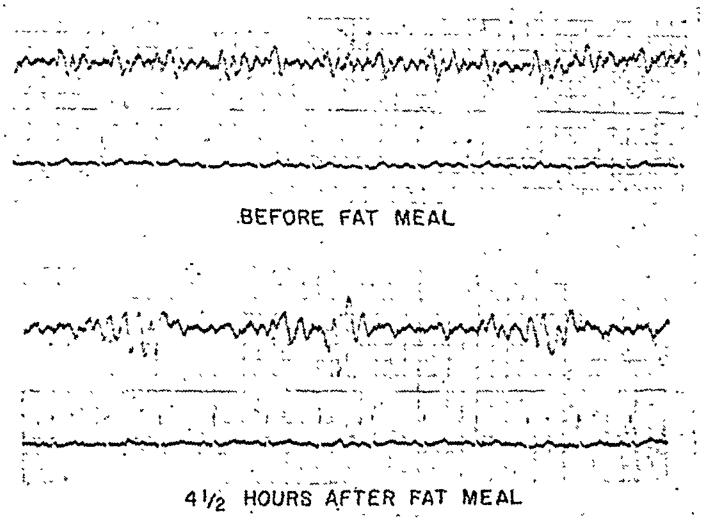

Fig. 5.—Ballistocardiograms obtained from patient who developed angina pectoris.

terfere with the inscription of the systolic ballistic complexes. The patient was quite dyspneic at this time, and a prominent diastolic gallop, probably of the summation type, became audible and palpable at the cardiac apex.

Another example of the ballistocardiographic changes induced by the fat meal is shown in figure 5. These tracings were obtained from a 58-year-old female with coronary artery disease with old myocardial infarction and angina pectoris. Her control ballistocardiogram (fig. 5, top) shows grossly abnormal ballistic complexes with prominent respiratory variations in the amplitudes of systolic ballistic complexes. The record reproduced in figure 5, bottom, was made during one of her attacks of anginal pain four and one-half hours after taking the fat meal. The respiratory variations in the ballistocardiographic complexes have become greatly exaggerated. Furthermore, the over-all amplitude of many of the systolic complexes is markedly decreased. Hence, during expiration, one has great difficulty in identifying the systolic ballistic complexes. The large irregular groups of vibratory waves are produced by exaggerated respiratory movements because: (1) at the time of recording, these waves were found to correspond to heavy breathing the patient was exhibiting at that time, (2) the vibrations did not have a constant relationship with the QRS complexes in the electrocardiogram, and (3) they disappeared when the patient held her breath in any phase of respiration.

The series of tracings shown in figure 6 taken in a patient with hypertension and severe coronary artery disease give another example of the abnormal ballistic waves. The systolic ballistic complexes in the control record of this patient (fig. 6, top) appear to be fairly distinct and regular, although they may be a little low in amplitude. The diastolic waves are relatively small throughout. The tracings became grossly abnormal five hours after fat ingestion, several minutes after the onset of substernal distress. The ballistocardiogram became totally disorganized at this time, and it was impossible to identify any of the systolic ballistic complexes. During the test, we observed that most of the body movements were actually caused by exaggerated breathing. The bottom tracing was made while the patient was asked to hold her breath momentarily. This promptly eliminated a large number of the extraneous waves and permitted proper identification of the ballistic complexes. Analysis of the ballistocardiogram as shown in figure 6, bottom, indicates that during angina pectoris, in addition to the greatly increased respiratory movements, the following changes appeared: 1. The H waves became more prominent than before the attacks. 2. A large, roughly V-shaped, mainly footward wave (D) appeared in mid-diastole. Although this V-shaped wave did not approach the size of the diastolic wave shown in figure 4, bottom, they appeared to be quite similar in most respects.

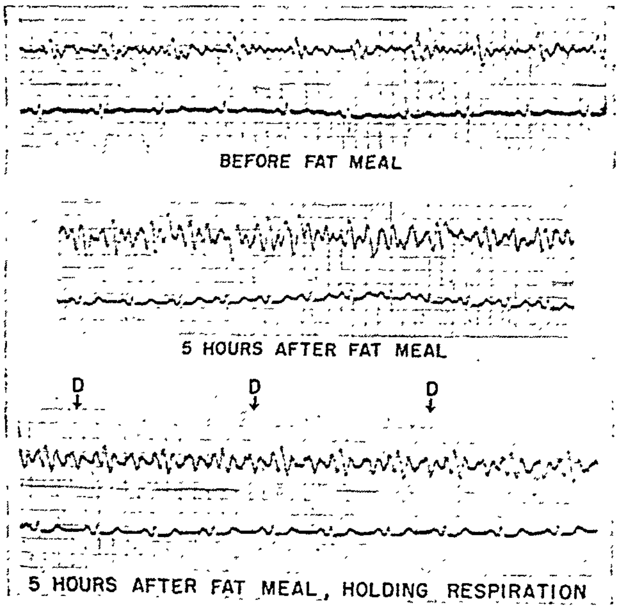

Fig. 6.—Ballistocardiograms of patient with coronary artery disease. The two lower tracings were recorded while the patient was having anginal pain. "D" in bottom tracing indicates the appearance of a V-shaped wave in diastole.

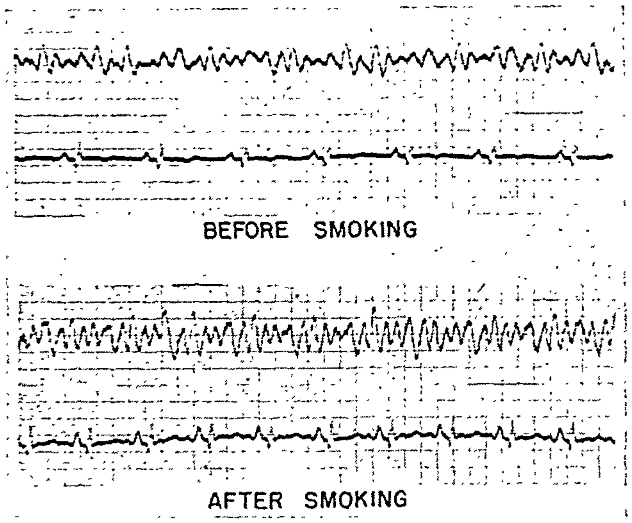

Fig. 7.—Ballistocardiograms of patient with coronary artery disease and healed myocardial infarction before and after smoking a standard brand cigarette.

Effect of Smoking on Ballistocardiogram.—A cigarette test was performed on 11 of these 14 patients, and a positive test consisting of a definite deterioration of the systolic ballistic complexes was obtained in 3 patients. An example of a positive cigarette test is shown in figure 7. The ballistocardiograms were made in a 62-year-old Negro with coronary artery disease and healed myocardial infarction before and after smoking one standard brand cigarette. None of the 11 patients developed typical anginal attacks after smoking.

COMMENT

The well-known clinical observation that patients with coronary artery disease tend to have exaggeration of symptoms shortly after a meal has been studied by a number of investigators.[3] It has been the opinion of most authors that the increased incidence of anginal pain after meals is probably due to an increase in cardiac work or to reflex constriction of coronary arteries as a result of gasenopathy and splenomegaly persisted for two to three weeks in the majority of cases. In none of these patients was jaundice observed.

An initial throat culture was obtained on all cases. Beta hemolytic streptococci were isolated in 14 (32.6%) and pneumococci in 24 (55.8%) of the cases. During the period of hospitalization, laboratory studies were performed at 7 to 10 day intervals. These included total white blood cell count and differential count; tests of one minute and total serum bilirubin, cephalin-cholesterol flocculation, thymol turbidity, bromsulphalein retention, sedimentation rate (Wintrobe), and heterophil antibody agglutination. In 22 cases the initial white blood cell count was 12,000 per cubic millimeter or greater. The initial differential counts were normal or showed an increase in neutrophils in 41 cases. In two cases there was an initial lymphocytosis of 50% or greater. After the patients' recovery from the upper respiratory infection, the total white blood cell count decreased to within a range of 5,000 to 11,000 per cubic millimeter, and in 22 cases a lymphocytosis of 50% or more developed. In seven cases there were 5 to 17% virocytes seen in the peripheral blood smear. In all cases the total serum bilirubin level was less than 1.5 mg. per 100 cc. Eleven patients had one or more abnormal liver function studies. Of the remaining 32 patients, liver function studies, which in 23 cases included three or more different tests, were normal. Heterophil antibody agglutinations were obtained in every case at least every 10 days during the period of hospitalization. In 39 cases the heterophil titer was either negative or positive in a dilution of 1:28 or less. In four cases the heterophil titer was initially positive in a dilution of 1:56 but decreased under further observation. In no case was a rise of heterophil antibody titer observed.

TABLE 1.—*Symptoms of Hepatitis in Forty-Three Patients*

Sudden onset	32	74.4
Gradual onset	9	20.9
Pain in epigastrium or liver area	41	95.3
Fatigue or malaise	39	90.7
Anorexia	31	72.1
Nausea	12	27.9

TABLE 2.—*Signs of Hepatitis in Forty-Three Patients*

	Patients	
	No.	%
Initial temperature 100 F or over	34	79.7
Initial pharyngitis or tonsillitis	41	95.3
Hepatomegaly	40	93.0
Tender liver	43	100.0
Lymphadenopathy	23	53.5
Splenomegaly	22	51.2

Pneumonia was present in two patients on initial examination. There was one case of bronchopneumonia, due to pneumococcus, and one case of diffuse patchy pneumonitis of unknown etiology. In one patient, during convalescence from hepatitis, appendicitis developed and an appendectomy was performed. All three of these patients made a complete recovery without any evidence of residual effects.

The initial upper respiratory infection was treated with intramuscular injections of procaine penicillin in 39 cases, oxytetracycline in 2 cases, and no antibiotic in 2 cases. After diagnosis of hepatitis, all patients were treated with bed rest and allowed bathroom privileges after the acute phase of their illness. A high-protein, high-carbohydrate diet with supplemental vitamins was given. Those patients with anorexia or nausea received glucose parenterally until the return of appetite.

The hospital stay of these 43 patients ranged from 18 to 155 days, with a median period of hospitalization of 28 days. The patients were considered to have recovered and were discharged from the hospital when they were asymptomatic concerning appetite and liver tenderness to fist percussion and when the sedimentation rate and any abnormal liver function studies had returned to normal. These men were placed on a regimen of restricted physical activity for varying periods of time, until they regained their strength and sense of well-being. Two patients required rehospitalization because of recurrence of anorexia, nausea, and pain in the liver area. One of these patients was rehospitalized two weeks after discharge from the hospital and the other one week after discharge; both subsequently made a complete recovery. At the time of discharge, 18 patients had a palpable liver, and 4 of these had a palpable spleen. Fourteen of these patients were followed on an outpatient basis for one to three months, and all abnormalities had disappeared at the end of the follow-up period except in two men who have nontender, palpable livers and normal liver function studies at the time of preparation of this paper. Four patients were not seen after release from the hospital.

TABLE 3.—*Laboratory Findings in Forty-Three Patients*

Bromsulphalein retention over 5% at end of 45 min. (performed in 35 cases)	6	17.1
Heterophil antibody titer greater than 1:56 dilution	0	0
Sedimentation rate (Wintrobe) over 10 mm. in 1 hr.	23	53.5

COMMENT

Anicteric cases of hepatitis have been repeatedly recognized in epidemics of infectious hepatitis.[2] The importance of such cases in the epidemiology of infectious hepatitis has been pointed out, and the possibility of chronic liver disease developing in unrecognized cases has been mentioned.[2c] Since sporadic cases of icteric hepatitis occur, it has been postulated that sporadic cases of anicteric-type hepatitis may also occur. In reviewing the English language literature, three reports of such cases occurring in adults have been found; one of 9 cases, one of 30 cases, and a third report of 4 cases.

A. **128**: 997-1003 (Aug. 4) 1945. (*b*) Finks, R. M., and Blumberg, R. W.: Epidemic Hepatitis With and Without Jaundice: Some Clinical Studies on 255 Patients Among Troops in a Combat Zone, Arch. Int. Med. **76**: 102-113 (Aug.) 1945. (*c*) Zimmerman, H. J.; Lowry, C. F.; Uyeyama, K., and Reiser, R.: Infectious Hepatitis: Clinical and Laboratory Features of 295 Cases, Am. J. M. Sc. **213**: 395-409 (April) 1947.

Reports of Anicteric Hepatitis.—In the report by Zimmerman and Thomas [1a] eight of the nine patients had an acute onset, and three had mild sore throats initially. Epigastric and right upper quadrant pain was a common complaint in these patients and, in contrast to the patients presented here, they complained of flatulence. All nine patients had a palpable and tender liver or "queasiness" in the right upper quadrant and had either cervical or generalized lymphadenopathy. The white blood cell count ranged from low to normal, and two patients had a lymphocytosis of 44% and 50% respectively. Three patients had 5% eosinophilia or greater. Urinary urobilinogen was increased, and the bromsulphalein retention was abnormal in all cases. Thymol turbidity and cephalin-cholesterol flocculation tests were abnormal in four and five cases respectively. The heterophil antibody agglutination test was negative in the four cases in which it was performed. The authors noted that liver enlargement persisted after lysis of the fever. Of the eight patients who were followed after the first week, four recovered completely within three to eight weeks. One was asymptomatic after 3 weeks but continued to have abnormal liver function studies for 10 weeks, and three had persistent abnormalities for over 4 months.

Denber and Leibowitz [1b] observed 30 sporadic cases of anicteric hepatitis over a one and one-half year period. The most common symptoms in their cases were persistent fatigue, anorexia, distaste for smoking, abdominal pain, headache, and nausea. Thirty-three per cent of these patients complained initially of sore throat, and 23% had signs of pharyngeal inflammation. The liver was palpable in 56%, tender in 79%, and both palpable and tender in 51% of the cases. There was splenomegaly in 27% of the cases, and in 56% there was either generalized or cervical lymphadenopathy. Virocytes were noted in 16 of 26 cases but did not number over 10% of the total number of cells. These cells were identical with Downey cells. The thymol turbidity in these 30 patients was abnormal in all cases, and the cephalin flocculation was abnormal in 86%. The total serum bilirubin level was slightly increased to 1.2 to 1.9 mg. per 100 cc. in 25% of the cases. All patients recovered within 10 days to 4 months, except one patient with a chronically active case who, it was suspected, may have had serum hepatitis. In 28 of the cases heterophil agglutinations were performed, and in 6 the heterophil was positive in a dilution over 1: 56 but was not of diagnostic titer after absorption studies.

Domenici [1c] reported four cases of hepatitis without jaundice or hepatomegaly. His cases undoubtedly represent some type of parenchymal liver disease, probably viral in origin; however, they differ from the cases reported here, from those reported by Zimmerman and Thomas, and from those of Denber and Leibowitz. Abnormal findings in his cases were tenderness to percussion over the liver area and tenderness in the right upper quadrant. The liver function studies were intermittently abnormal throughout the course of the disease. The illness in these four cases was prolonged with psychological disturbances and lasted from four to six months.

Initially, the patients presented here had symptoms of an upper respiratory infection. This responded well to antibiotic treatment, and the patients became asymptomatic in this regard. In the majority of cases it was not until after the upper respiratory infection had been cured and the temperature had decreased to normal that the symptoms of liver disturbance became prominent. In contrast to the previously recognized cases of acute anicteric hepatitis, only a few of the patients presented here showed evidence by laboratory studies of liver dysfunction; however, in all cases, there were definite signs and symptoms of inflammation of the liver, frequently accompanied by other evidence of generalized disease.

Etiology.—At the present time the etiological agent of this illness is unknown. Three possibilities as regards etiology have been considered. These cases could represent an immune response of the liver to an acute infection, a viral hepatitis related to either the infectious or the serum hepatitides, or a disease related to infectious mononucleosis. The incidence of presenting upper respiratory infections is very high in this group of cases and considerably higher than that reported in the three other studies of sporadic anicteric hepatitis. It is known that the liver may become enlarged and tender after acute infections.[3] It has been stated that inflammatory changes in the liver may occur after sore throats and other acute infections as a tissue immune reaction, similar to that occurring in the kidneys in acute nephritis.[4] In such cases these abnormalities are usually transient, and persistence for 10 to 14 days is considered evidence of primary liver disease.[3] That the illness presented here is a response of the liver to acute infection is unlikely, since in 17 cases the onset of the upper respiratory infection and the evidence of liver disease appeared simultaneously, and in all cases the evidence of liver abnormalities persisted for at least two weeks. Instead, it seems most likely that the prodromal stage of this illness may predispose to upper respiratory infections.

In the other reports of anicteric hepatitis the authors have postulated that a virus was responsible for the illness.[5] In view of the normal or slightly low white blood cell count, the lymphocytosis, and the appearance of virocytes in some of the patients during the course of their hepatitis and after the disappearance of the upper respiratory infection, it would seem likely that these cases also represent a virus disease. Except for the lack of abnormal liver function studies and high incidence of preceding upper respiratory infections, these cases closely resemble the anicteric cases accompanying epidemics of infectious hepatitis.[2] In addition, cases of anicteric hepatitis similar to the cases presented here have been produced in human volunteers by the administration of material known to contain the virus of either infectious or

serum hepatitis.[6] Anicteric hepatitis also occurs when infectious hepatitis is attenuated with gamma globulin,[7] and such cases also closely resemble those presented here. Thus, this disease may be a mild or attenuated form of infectious hepatitis.

The possibility that these cases may be a mild form of serum hepatitis has also been considered. Fifty-eight per cent of these patients had less than six months of military service and had had some type of vaccine administered parenterally at the time of entry into service; however, during the period of observation 10 cases of infectious hepatitis with jaundice were encountered, while there were no proved cases of serum hepatitis. The acute onset of the illness as well as the lack of any confirmed common icterogenic source of infection also is against this likelihood.

The greatest difficulty was in differentiating this syndrome from infectious mononucleosis. During the period of observation, 24 proved typical cases of infectious mononucleosis were encountered. In the majority of those cases there were abnormal liver function studies. The diagnosis of infectious mononucleosis was not confirmed in the cases presented here, despite the clinical similarity, because of the low percentage and lack of persistence of virocytes in the differential smear, plus the lack of a positive heterophil agglutination titer despite repeated examinations.[8] The possibility that these cases represent an atypical seronegative form of infectious mononucleosis has been considered. This question cannot be resolved until a specific diagnostic test for the etiological agent of both infectious hepatitis and infectious mononucleosis is developed.

Unless one considered the possibility of liver disease, these cases might easily have been misdiagnosed as unusual upper respiratory infections or as influenza. It is important that these cases be correctly diagnosed. They will help clarify the epidemiology of hepatitis as more specific tests are developed. In addition, because this illness may represent a type of infectious hepatitis, cases should be recognized so that the patients may be temporarily eliminated from the role of blood donors. The duration of the carrier state in infectious hepatitis has been shown in some cases to last for years.[9] With the ever-increasing popularity of the parenteral administration of blood derivatives, all possible icterogenic sources must be eliminated if a continual pyramiding of cases of homologous serum hepatitis is to be prevented.

Sequelae.—In addition, the possible long-term sequelae of this illness are still in doubt. There is a large body of evidence that points to viral hepatitis as a factor in the pathogenesis of chronic liver disease,[10] especially as alcoholism assumes a minor role in certain areas.[11] Many patients with cirrhosis have no history of jaundice,[12] which leads to speculation on the importance of anicteric attacks of hepatitis at the onset of the disease.[9] Despite the apparent benignity of the disease in this conservatively treated series, there were two patients who had evidence of activity four months from the onset, placing their disease in the chronic active phase as characterized by Barker.[10a] Both of these patients completely recovered; however, it should be pointed out that all of the cases presented here were in healthy young men who were placed on a regimen of limited activity for as long as necessary. In civilian populations with an older age group, or where continued exposure of the liver to other insults may occur during the disease, a complete recovery may not be the rule.

SUMMARY

The 43 patients with anicteric hepatitis associated with upper respiratory infections reported on showed typical symptoms and signs of parenchymal liver disease; however, only a minority of the patients presented any laboratory evidence of liver dysfunction. It is probable that these cases represent a virus disease related either to infectious hepatitis or to infectious mononucleosis. These patients were treated in the usual manner, with bed rest; high-caloric, high-protein diet; and glucose administered parenterally, when indicated. All patients responded well to treatment, and follow-up to complete recovery was accomplished in a majority of cases. The importance of these cases is emphasized in reference to the epidemiology of hepatitis, elimination of patients with this disease as potential blood donors, and the possible antecedence of this illness to chronic liver disease.

Common Sense in Cancer.—Surgical attacks on highly malignant tumors, like trauma to streptococcal infections, may do more harm than good. They break the natural barriers. They spread the disease. When we remember that the blood and lymphatic vessels of highly malignant tumors are filled with tumor cells, it is clear that it is not often possible to excise such tumors completely. They have extended diffusely into the tissue spaces. They are systemic diseases. . . . Not all cancers are as virulent as hemolytic streptococci. Some are like staphylococci—locally destructive, tending to remain in one area. These cancers are like abscesses. They are amenable to surgical treatment. Squamous cell cancers, papillary cancers of the thyroid, and many of the cancers of the colon are biologically predetermined to remain localized for long periods and to metastasize chiefly to the regional lymph nodes. Many of them can be controlled by adequate excision of the primary tumor and its zone of lymphatic metastasis. The people who consider surgical attack harmful are wrong about these tumors. Most of them are curable. The public does not distinguish between various types of cancer. They lump cancers together under one name. That is why the cancer problem is not understood. But if we are to settle the confusion in the mind of the public, we must first settle the confusion in our own minds. We must study the natural history of cancers.—G. Crile Jr., M.D., Common Sense in Cancer, *Postgraduate Medicine*, April, 1955.

PARADOXICAL ACTION OF GLYCERYL TRINITRATE (NITROGLYCERIN) IN CORONARY PATIENTS

Henry I. Russek, M.D., Karl F. Urbach, M.D., Staten Island, N. Y.
and
Burton L. Zohman, M.D., Brooklyn, N. Y.

For more than 75 years, no drug has proved superior to glyceryl trinitrate (nitroglycerin) in warding off or cutting short attacks of angina pectoris. Most observers have attributed the beneficial action of this agent to its vasodilating effect on the coronary arteries. On the other hand, while favorable therapeutic response in most patients is an established fact, clinical experience has proved that, in certain cases, the use of nitrites is not followed by clinical improvement [1] and may even cause untoward effects. A considerable number of reports in the literature make it clear that glyceryl trinitrate is not a perfectly harmless drug and that there exists a significant incidence of collapse, syncope, and less severe reactions of cardiovascular nature after its administration.[2] Usually such reactions are ascribed either to overdosage or to an individual sensitivity of the patient. The causes of such reactions are readily discernible, however, if one considers the pharmacological actions of this drug on the whole of the cardiovascular system rather than on the coronary circulation alone. Experimental work has shown that nitrites produce a general vasodilatation that is most marked in the postarteriolar vascular bed. Weiss and associates [2d] have demonstrated that capillaries and venules are strongly dilated by administration of sodium nitrite which causes a diminution in the tone of the venous reservoir, diminished venous return to the heart, and peripheral circulatory collapse. Little information is available about the effect of the nitrites on the output and work of the human heart. Wegria and associates,[3] in recent studies made with a low-frequency ballistocardiograph, concluded that cardiac work per beat and per minute is increased by glyceryl trinitrate. Their findings suggest that glyceryl trinitrate relieves the anginal pain of myocardial ischemia by increasing the coronary flow relatively more than the work of the heart. Brandt and associates,[4] however, using the slit-kymograph have offered strong evidence that glyceryl trinitrate decreases heart volume and stroke volume. As a result of increase in heart rate the net effect on minute volume flow is insignificant in most subjects but may result in a rise of 30% in subjects whose rates are markedly accelerated. The fact that the decrease in stroke volume was more marked in erect than in recumbent subjects gave confirmation to the findings of Weiss and associates [2d] that the decrease is due primarily to venous pooling and reduced return to the heart. Inasmuch as any disturbance in cardiac function due to poor venous return appears to aggravate angina, it must be assumed that glyceryl trinitrate is effective in spite of its action in decreasing cardiac filling.[4] Moreover, since glyceryl trinitrate has little effect on cardiac work per minute, its favorable action in angina pectoris must result from better flow through the larger coronary collateral arteries. The view of Raab [5] that glyceryl trinitrate may act in a different manner, namely, by interfering with the metabolic, anoxia-producing effects of the sympathomimetic amines on the myocardium, has not been confirmed by other investigators.[6] It would appear therefore that glyceryl trinitrate exerts specific effects on coronary blood flow, venous return to the heart, stroke volume, peripheral resistance, cardiac rate, and blood pressure. Although occasionally some of these changes in the vascular system are so pronounced that they are found to vitiate or overbalance the effect of coronary vasodilatation (either by decreasing coronary flow or by increasing the work of the heart), they are usually of such mild degree or so well compensated for by reflex mechanisms that the over-all effect is beneficial for the coronary circulation. When the reflex changes compensating for peripheral venous stasis induced by glyceryl trinitrate fail, however, circulatory collapse and syncope may ensue. Reports of less apparent untoward phenomena of cardiovascular nature following nitrite administration have been few. Dewar and Grimson [2g] observed a case of angina pectoris in which glyceryl trinitrate actually induced pain and produced depression of the S-T segments at rest comparable to the S-T segment depression caused by exercise. No explanation for this phenomenon was offered. Electro-

cardiographic changes after inhalation of amyl nitrite have been reported in the literature by various authors. Goldberger [7] attributes them to rotation of the heart resulting from its decrease in size and contends that similar, if not identical, findings are produced by deep inspiration. Nordenfelt [8] considers the alterations in the electrocardiogram after inhalation of amyl nitrite to be similar to those occurring in the change from the supine to the erect position. Contro and associates,[2h] on the other hand, found that amyl nitrite inhalation often produced electrocardiographic changes that were similar to those obtained with an exercise test in the same patients. They suggest that, in spite of coronary vasodilatation, the tachycardia and fall in blood pressure induced by the drug may result, paradoxically, in myocardial ischemia. The purpose of the present report is to record a series of cases in which untoward effects from glyceryl trinitrate were observed on electrocardiographic tracings and to attempt an explanation of the mechanism involved.

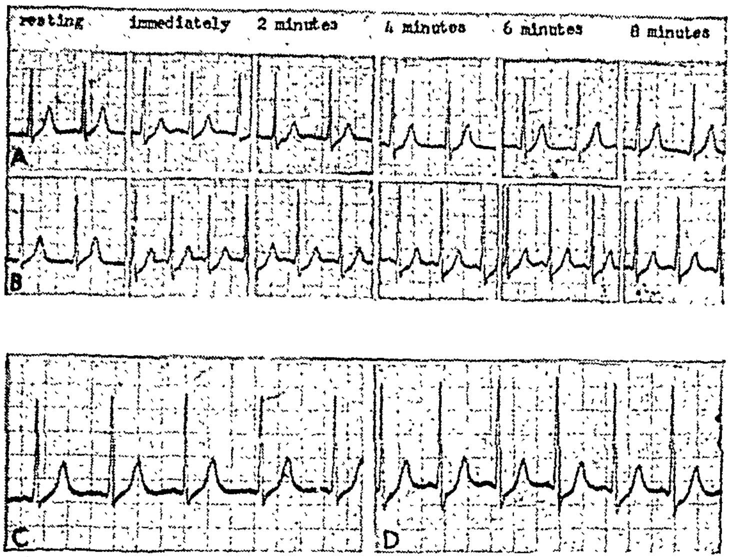

Fig. 1 (case 1).—Master tests (lead V_4) showing *A*, control response and *B*, response after premedication with glyceryl trinitrate. Note more abnormal response in *B*. *C* and *D*, resting electrocardiogram (lead V_4) with patient recumbent: *C*, before glyceryl trinitrate and *D*, five minutes after 0.4 mg. (1/150 grain) of glyceryl trinitrate sublingually.

METHOD

The modifying effect of varying doses of glyceryl trinitrate (0.2 to 1.2 mg. [1/300 to 1/50 grain]) upon the electrocardiographic response to standard exercise was studied in 158 patients with coronary disease who showed consistently abnormal responses in control tests. Of this number, 154 were men between the ages of 32 and 77 years and 4 were women, 48, 51, 56, and 62 years respectively. Twenty-two of the total had suffered a clinical episode of acute myocardial infarction previously, while 51 presented classic symptoms of angina pectoris at the time of study. Arterial hypertension was present in about 40% of the patients. In all instances a hypodermic tablet of glyceryl trinitrate in varying dosage was administered sublingually five minutes before commencement of the Master two-step test, after which the results were compared with those obtained in control studies without prior medication. In subjects in whom such comparison indicated a paradoxical response to glyceryl trinitrate, careful study was made of the effect of the drug on the resting electrocardiogram.

RESULTS

With a dose of 0.4 mg. (1/150 grain) administered sublingually five minutes prior to exercise, 105 patients showed a completely normal response, 26 an improved response, 11 no significant change, and 16 patients even greater abnormalities than were observed in control tracings. Among the 131 patients responding favorably to 0.4 mg., there were 16 who showed less dramatic results or a paradoxical response when larger doses were employed (0.6 to 1.2 mg. [1/100 to 1/50 grain]). On the other hand, the majority of these patients responded as well to 0.2 or 0.3 mg. (1/300 or 1/200 grain) as they did to 0.4 mg. (1/150 grain). Five of the 11 patients who showed no significant change with 0.4 mg responded favorably to larger doses of this drug. It therefore became apparent that individualization of dosage is an important prerequisite to rational therapy in angina pectoris. Moreover, even in the patients who showed a paradoxical response to ordinary doses of glyceryl trinitrate, adverse effects did not appear with smaller amounts of the drug. The following cases are representative of the 16 patients who showed paradoxical response to 0.4 mg. of glyceryl trinitrate.

REPORT OF CASES

CASE 1.—A 56-year-old white male who had suffered an attack of myocardial infarction in 1947 presented no complaints referable to the cardiovascular system. The 12-lead standard electrocardiogram was consistent with the diagnosis of an old posterior myocardial infarct. In studying the effect of exercise on the electrocardiogram (with and without premedication with glyceryl trinitrate) it was observed that the S-T segment depression induced by effort was of greater magnitude and duration when this drug had been employed. It can be seen in figure 1*A* and *B* that the administration of glyceryl trinitrate (0.4 mg.) five minutes before the performance of the exercise test resulted in a more abnormal electrocardiographic response than that observed in the control study without such medication. This unexpected and apparently paradoxical response prompted us to study the effect of a similar dose of glyceryl trinitrate on the patient's resting electrocardiogram. Figure 1*C* and *D* shows that the administration of this drug with the patient in the recumbent position resulted in S-T segment depression of even greater magnitude than that produced by exercise alone (fig. 1*A*). This abnormality gradually disappeared within the next 12 minutes, while the blood pressure fell from a control value of 142 mm. Hg systolic and 90 mm. Hg diastolic to 108 systolic and 80 diastolic 9 minutes after the administration of glyceryl trinitrate (table 1). The heart rate increased from a control value of 94 to 120 beats per minute in 5 minutes then gradually fell to the control level again in 15 minutes (table 1). The administration of glyceryl trinitrate to this patient even in a dose as small as 0.2 mg. consistently produced symptoms of dizziness, headache, and nausea while he was in the upright position. Reclining promptly relieved the patient of his symptoms.

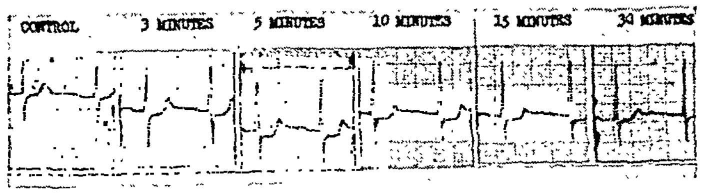

Fig. 2 (case 2).—Effect of 0.4 mg. (1/150 grain) of glyceryl trinitrate on resting electrocardiogram (V_4). Depression of the S-T segment persisted up to 30 minutes.

Case 2.—A 67-year-old white male had suffered from angina pectoris for approximately four years. More recently he noted that the attacks had become more severe and were more easily induced by effort or excitement. The standard 12-lead electrocardiogram with the patient recumbent showed slight depression of the precordial S-T segments. This depression became marked in lead V_4 5 minutes after administration of glyceryl trinitrate (0.4 mg.) and persisted up to 30 minutes (fig. 2). The blood pressure dropped from a control level of 120 mm. Hg systolic and 70 mm. Hg diastolic, before administration of the drug, to a low of 98 systolic and 75 diastolic seven minutes after the drug was taken (table 2). The heart rate increased from 79 beats per minute before glyceryl trinitrate to a maximum of 91 beats per minute 7 minutes after its administration, returning to the control level in 30 minutes (table 2). The electrocardiographic changes induced by glyceryl trinitrate were similar to those that developed after the performance of a modified exercise test by this patient. The administration of dihydroergocornine (0.5 mg.) subcutaneously failed to prevent the paradoxical response to glyceryl trinitrate.

30	130/80	92

* With patient recumbent.

Case 3.—A 57-year-old Chinese male with diabetes mellitus presented no symptoms referable to the cardiovascular system. Although routine cardiac examination as well as electrocardiographic study revealed no abnormalities, results of the Master two-step test were positive (fig. 3*A*). When glyceryl trinitrate (0.4 mg.) was administered five minutes before exercise, the tracings (fig. 3*B*) showed T-wave inversion of greater magnitude and duration than that seen in the control test. It was also noted in this patient that sitting up resulted in inversion of the T wave in precordial leads V_4 to V_6, while standing extended the T-wave inversion to V_2. The administration of dihydroergocornine (0.5 mg.) failed to prevent the alterations induced by exercise or change in body position. Exercise, standing or sitting up, or administration of glyceryl trinitrate did not produce any untoward subjective symptoms in this patient. On the suspicion that venous pooling might be the cause of the described T-wave inversions, tight elastic bandages were applied to the patient's abdomen and/or lower extremities. Figure 3*C* and *D* shows clearly that the T-wave inversion due to standing was prevented by leg bandages (wrapped from feet to groin) whereas an abdominal binder alone was ineffective. It is seen from figure 4 that the application of leg bandages also prevented the T-wave inversion induced by glyceryl trinitrate when the patient was recumbent but failed to exert such an effect when the patient was in the sitting or standing position. Although the electrocardiogram indicated that leg bandages were superior to an abdominal binder with the patient erect, the ballistocardiogram revealed the abdominal binder to be more effective than leg bandages when the patient was recumbent (fig. 5).

COMMENT

The findings of this study indicate that, although glyceryl trinitrate is the most useful drug in the treatment of angina pectoris, it is an agent that possesses latent potentialities for adverse effects in this disease. Ten per cent of the patients in this study showed unfavorable electrocardiographic responses to the usual therapeutic dose of 0.4 mg. (1/150 grain). An additional 6% reacted paradoxically when larger dosage was employed. In all of these cases the electrocardiographic changes induced by glyceryl trinitrate were similar to those observed with the exercise test. It would seem therefore that a threshold dosage level may exist in many patients above which the resultant relaxation of the venous reservoir could reduce cardiac output and coronary flow sufficiently to outweigh beneficial effects derived from direct

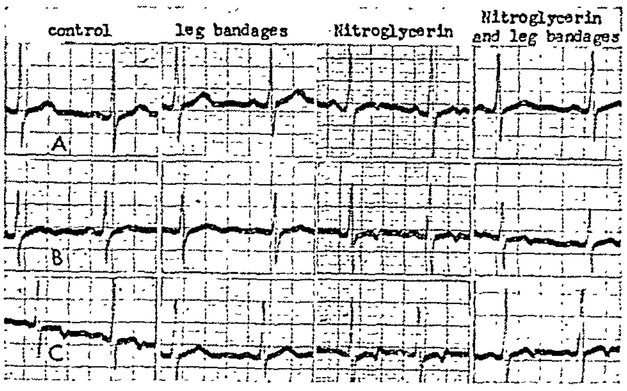

Fig. 4 (case 3).—Electrocardiograms (lead V_4) showing the effect of leg bandages in preventing T-wave changes associated with standing or induced by glyceryl trinitrate. Note that bandaging counteracted the effect of glyceryl trinitrate only when the patient was recumbent. *A*, reclining; *B*, sitting; and *C*, standing.

coronary vasodilatation. That these induced changes in the electrocardiogram after the administration of glyceryl trinitrate as well as after the assumption of the erect posture in some cases are not due to rotation of the heart or increased tonus of the sympathetic nervous system also appeared to be established. Thus deep inspiration failed to evoke similar electrocardiographic changes, while sympatholytic agents failed to prevent their appearance in the usual manner. On the other hand, the application of elastic bandages to the lower extremities prevented the changes occurring on standing and, to a lesser degree, those induced by glyceryl trinitrate. The genesis of the electrocardiographic alterations after the change from the supine to the erect position appeared to be similar to that underlying the glyceryl trinitrate response; venous pooling in the lower extremities seemed to be the major factor in both instances. It is of further interest that in the erect position the venous reservoir of the lower extremities appeared to play a greater role than the splanchnic area with respect to the improvement in venous return to the heart obtained by bandaging. On the other hand, in the horizontal position, the abdominal binder showed a more favorable effect on ballistic pattern than leg bandages. Inasmuch as anginal attacks are more usually encountered in patients who are active and erect, the possible therapeutic value of elastic bandages for the lower extremities in some cases would seem to deserve consideration. The evidence suggests that there may be a better rationale for the application of leg bandages than of an abdominal binder. Indeed, best results might be achieved by the combined use of both procedures.

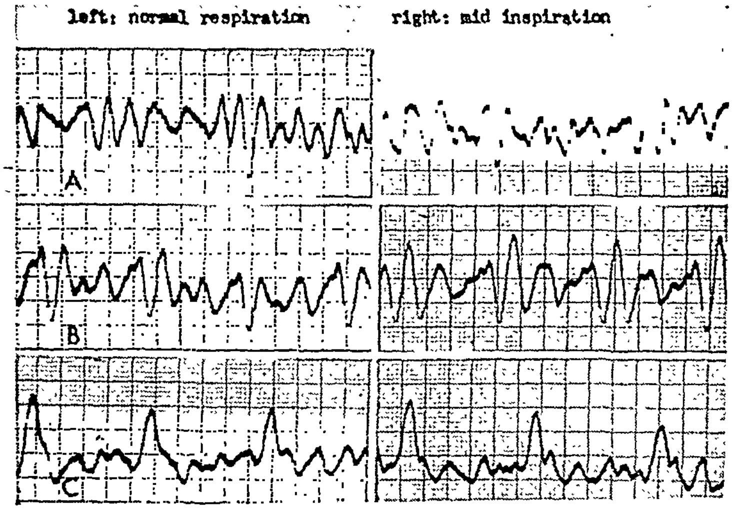

Fig. 5 (case 3).—Ballistocardiograms showing the influence of an abdominal binder or leg bandages on ballistic pattern. *A*, control; *B*, abdominal binder; and *C*, elastic bandages to legs. The most satisfactory e is seen in *B*.

The observations of this study appear to correlate well with the conclusions of Weiss and associates [2d] and Brandt, Caccese, and Dock [4] that glyceryl trinitrate decreases heart volume and stroke volume as a result of venous pooling and reduced return to the heart. The action of glyceryl trinitrate on the venous system suggests a possible therapeutic application of this effect in congestive heart failure. When used alone or in conjunction with tourniquets to the extremities, the administration of glyceryl trinitrate, perhaps in large dosage, many utilize the peripheral venous system as a reservoir, decrease the circulating blood volume, and reduce the size of the heart. Not only in the therapy of acute left ventricular failure but in its prophylaxis prior to contemplated exertion in patients with diminished cardiac reserve, this procedure has appeared to have distinct value.

This study indicates that the optimum dosage level for glyceryl trinitrate in most patients with angina pectoris is 0.2 to 0.3 mg. (1/300 to 1/200 grain) sublingually. Larger doses frequently induce unpleasant side-effects without improving therapeutic response or exert an adverse action upon the heart. In our opinion only the hypodermic tablet should be employed; the preparation (triturated) for oral use is ineffectual even in massive dosage orally or sublingually, and its use should be discontinued. Inasmuch as paradoxical effects from glyceryl trinitrate are encountered in patients with angina pectoris with therapeutic as well as with excessive amounts of the drug, establishment of the optimum dosage level in the individual case should constitute an important objective of therapy. Moreover, the precipitation of acute myocardial infarction should be recognized as a definite risk from overdosage during therapy of the anginal attack. Venous pooling in the lower extremities, diminished venous return to the heart, tachycardia, and fall in blood pressure are actions of the drug that not only interdict its use in acute myocardial infarction but reflect its danger when carelessly administered in angina pectoris. There can be no doubt that overdosage during self-medication for a severe paroxysm of angina pectoris is responsible for the precipitation of acute myocardial infarction in many patients.

SUMMARY AND CONCLUSIONS

A study of the effect of varying doses of glyceryl trinitrate (nitroglycerin), 0.2 to 1.2 mg. (1/300 to 1/50 grain), on the electrocardiographic response to standard exercise (Master two-step test) was undertaken in 158 patients with coronary disease who showed consistently positive changes in control studies. It was found that with a dose of 0.4 mg. (1/150 grain) given sublingually five minutes before exercise, 131 patients (83%) responded favorably, 11 patients (7%) showed no significant effect from the drug, and 16 patients (10%) demonstrated even greater abnormalities than were apparent in the electrocardiographic records of control tests. This study appears to indicate that individualization of dosage is an important prerequisite to rational therapy in angina pectoris.

The effect of glyceryl trinitrate on the resting electrocardiogram in 16 patients who responded paradoxically to the drug when given exercise tests caused us to make the following observations: 1. In all cases the electrocardiographic changes induced by glyceryl trinitrate were similar to those that were recorded in the performance of the Master two-step test. 2. Paradoxical response to glyceryl trinitrate is caused by venous pooling in the lower extremities, diminished venous return to the heart, and reduced coronary blood flow in spite of concomitant coronary vasodilatation. In some instances, change from the recumbent to the erect posture produced electrocardiographic alterations that were similar to those evoked by this drug. Elastic bandages on the lower extremities prevented the changes occurring on standing and to a lesser degree those induced by glyceryl trinitrate.

The possible value of an abdominal binder and leg bandages in angina pectoris is suggested by these observations, which indicate, however, that the legs are a more important venous reservoir than the splanchnic area when the patient is erect. 3. The action of glyceryl trinitrate on the venous system may have therapeutic application in the prophylaxis and treatment of acute congestive heart failure, in which condition decrease in venous return and diminution in heart size are important objectives of therapy. 4. Although glyceryl trinitrate is the most useful agent in the treatment of angina pectoris, it has not been adequately appreciated that the drug also possesses latent potentialities for adverse effects in this disease. The optimum dosage for most patients is 0.2 to 0.3 mg. (1/300 to 1/200 grain) sublingually. The precipitation of acute myocardial infarction is more than a theoretical danger from overdosage during treatment of the anginal attack.

CLINICAL NOTES

CORTICOTROPIN IN SEVERE ANGINOSE INFECTIOUS MONONUCLEOSIS

Capt. William Mandel
Lieut. R. J. Marilley Jr.
and
Lieut. L. M. Gaines Jr., (MC), U. S. A. F.

Respiratory obstruction resulting in death in one instance and requiring tracheotomy in eight instances has been reported in patients with anginose infectious mononucleosis. This is a report of a patient with infectious mononucleosis in whom the symptoms and signs of respiratory obstruction were severe enough to warrant a tracheotomy but who instead was first treated by intravenously administered corticotropin (ACTH).

REPORT OF CASE

An 18-year-old white male was first seen because of the onset of sore throat, dysphagia, hoarseness, swelling of the neck, weakness, malaise, headache, chills, and generalized aching of two days' duration. A diagnosis of "pharyngitis" was made at the onset of his illness, and he was given 300,000 units of procaine penicillin intramuscularly for two days. When the symptoms progressed, the dose of penicillin was increased to 600,000 units daily. Because he failed to respond to this treatment, he was admitted to the hospital. His history revealed that he had had the usual childhood diseases without known sequelae. His general health had been good, and he had not been jaundiced.

The patient was an acutely ill, well-developed, well-nourished young male. His skin was warm and flushed. His temperature was 102.4 F, pulse 118, and respiratory rate 32 per minute. He was in moderate to marked respiratory distress and was breathing through his mouth. His respirations were short, grunting, and shallow in nature. He was not cyanotic. There was retraction of the intercostal spaces with inspiration. There was no icterus of the skin or sclerae. His neck was markedly enlarged from two to three times its normal size by many discrete tender lymph nodes. It was similar to the bull-neck seen in patients with Hodgkin's disease. The uvula, soft palate, and pharyngeal areas were markedly reddened, hyperemic, and edematous. There were no exudates present. There was marked tenderness and moderate enlargement of the lymph nodes in the anterior and posterior cervical chains and in the axillary, epitrochlear, and inguinal areas. The heart was normal except for sinus tachycardia. There was slight distention of the abdomen, and it was tender to palpation in both the right and left upper quadrant areas. The liver was not definitely felt. The spleen was tender and was felt 4 cm. below the left costal margin. The neurological examination was normal. The remainder of the physical examination was normal.

The serologic test for syphilis, hemoglobin, red blood cell count, urinalysis, chest roentgenogram, blood urea nitrogen, and carbon dioxide-combining power were normal. The white blood cell count was 20,750 cells per cubic millimeter, with the differential count showing 61% lymphocytes and 33% neutrophils. The blood smear showed some prolymphocytes and Türk's cells as well as atypical lymphocytes that were suggestive, though not diagnostic, of infectious mononucleosis. The sedimentation rate was 13 mm. per hour. The cephalin-cholesterol flocculation was 3+ in 24 and 48 hours. The direct and total serum bilirubin and the thymol turbidity were normal. The heterophil antibody test was positive in a dilution of 1:448. After absorption with guinea pig kidney, the dilution was positive in 1:228, and there was no titer after absorption with beef red blood cells. On the third hospital day, atypical lymphocytes that were diagnostic for infectious mononucleosis appeared.

A tracheotomy was considered soon after hospital admission. Prior to this, it was felt that the effects of intravenous administration of corticotropin would be evaluated. The medicament was given daily over an 8 to 14 hour period for five days. The following daily doses were given: 15, 10, 7.5, 5, and 2.5 mg. for a total of 40 mg. The patient appeared almost well on the morning of the second hospital day—16 hours after admission. His temperature was normal. There was a noticeable decrease in the size as well as in the tenderness of his neck. His voice was no longer hoarse, and he was able to swallow without marked difficulty. The spleen could not be felt, and the abdomen was soft and nontender. This improvement continued throughout his hospital stay. There was a gradual fall in the total white blood cell count to within normal limits. The lymphocytosis, which varied from 40 to 72%, persisted throughout the hospitalization. There was a gradual fall in the sedimentation rate to normal. The heterophil titer remained unchanged. Except for weight gain, there were no adverse effects from the medication. The patient's course in the hospital was uncomplicated, and he was discharged 11 days after admission. He was seen one and three weeks after discharge and was well at both times. The laboratory studies on his last visit revealed a normal white blood cell count. There was a 45% lymphocyte count, and the atypical lymphocytes were still present. The sedimentation rate was 4 mm. per hour; the heterophil antibody test was 1:448, and it was 1:112 after guinea pig kidney absorption. The cephalin-cholesterol flocculation was 1+ in 24 and 2+ in 48 hours. The physical examination was normal except for small, firm, nontender cervical, axillary, and inguinal lymph nodes.

COMMENT

Librach,[1] in 1951, performed a tracheotomy for the relief of respiratory obstruction in a patient with infectious mononucleosis. He reported six similar cases. An additional case has since been added by Delaney and Nelson.[2] Two patients were treated, prior to the tracheotomy, with diphtheria antitoxin [3] and one with diphtheria

---

antitoxin and neoarsphenamine.[4] These may have contributed to the glottal edema and respiratory distress. In the one reported death [3b] due to respiratory obstruction, the patient had been treated with diphtheria antitoxin, and the author felt that this might have had some part in the fatality. In the past, cases of infectious mononucleosis were probably frequently diagnosed as diphtheria, and tracheotomies done for the latter disease may actually have been performed for severe anginose infectious mononucleosis.

Bender and Houghton [5] treated 11 patients with infectious mononucleosis with intramuscularly administered corticotropin. They reported prompt reduction in the pharyngeal inflammatory reaction and in the severity of the illness. They recommended use of this drug when the disease process was of more than average severity. Doran and Weisberger [6] reported one patient whose disease was complicated by thrombocytopenia, azotemia, and liver failure, and who improved coincident with the administration of corticotropin. They also suggested that the medicament be given in severe and complicated cases of infectious mononucleosis. Fiese and co-workers [7] reported a patient with virus encephalomyelitis (Guillain-Barré syndrome) associated with infectious mononucleosis who improved with the administration of corticotropin. Brutsche and Naegele [8] reported one patient who was seriously ill with infectious mononucleosis and who rapidly improved after the intravenous administration of corticotropin.

The results of the treatment in our case were similar to he experience of the above authors. There was marked and rapid clinical improvement associated with a decrease in the pharyngeal edema and a disappearance of the symptoms and signs of respiratory obstruction. This avoided the possible need for a tracheotomy. There was a decrease in the size of peripheral lymph nodes and of the spleen. There was no recurrence of the symptoms or recurrence of the signs of the disease when the medication was stopped.

SUMMARY

Corticotropin (ACTH) was administered intravenously to a patient with severe anginose infectious mononucleosis. This produced a rapid decrease in the signs and symptoms of the disease. A tracheotomy that had been contemplated for relief of the respiratory distress was no longer required. The use of corticotropin is advised in the patient with infectious mononucleosis who has marked respiratory difficulty.

INJURY AND DEATH FROM RED FUMING NITRIC ACID

Capt. A. J. McAdams Jr. (MC), U. S. Army (Res.)
and
Stephen Krop, Ph.D., Army Chemical Center, Md.

Serious injury by concentrated nitric acids is not infrequent, accounting for a significant number of the cases of disability and death from hazardous chemicals.[1] Toxicologically, the two major forms may be regarded as identical, since they are both extremely corrosive and since both emit dangerous fumes. Red fuming nitric acid contains dissolved oxides of nitrogen ("nitrous fumes"), which are toxic; decomposition of the acid on contact with oxidizable material liberates more oxides of nitrogen. White fuming nitric acid, though containing little dissolved oxides of nitrogen, decomposes on contact with oxidizable material just as red fuming nitric acid and also liberates oxides of nitrogen. The growing utilization of red fuming nitric acid (RFNA) by industry and by the armed services makes timely a brief restatement of its hazards, how they should be avoided, and what to do in case of exposure. Illustrative case histories are given.

The concentrated nitric acids are extremely corrosive fuming liquids, with varying amounts of dissolved oxides of nitrogen, which are evolved as reddish-brown fumes with small amounts of acid vapor. Nitric oxide in contact with air is fairly rapidly oxidized to nitrogen dioxide. Nitrogen dioxide readily polymerizes to nitrogen tetroxide, the inhaled fumes at body temperature consisting of approximately 30% NO_2 and 70% N_2O_4. These oxides form nitric acid on contact with water.[2] The fuming nitric acids constitute a definite hazard, causing injury by liquid contact with body surfaces and by inhaled fumes. Yellow discoloration of the skin follows brief contact, while more than momentary contact produces severe, slow-healing burns. Contact with the eyes may result in corneal injury with permanent visual impairment. Severe pulmonary injury may result from inhalation of "nitrous fumes." Four distinct clinical pictures in acute poisoning by inhalation of "nitrous fumes" have been described [3]: (1) the irritant gas type, in which there are signs of local irritation followed by a latent period of a few hours and then the development of pulmonary edema with death in one to two days; (2) the reversible type, in which there is a rapid succession of dyspnea, cyanosis, vomiting, vertigo, and sometimes unconsciousness; (3) the shock type, in which there is a very rapid onset of signs of suffocation, convulsions, and cessation of breathing; and (4) a combined form, in which there are early cerebral symptoms that subside after removal from the fumes. However, after a latent period of a few hours, pulmonary edema develops.

From the Chemical Corps Medical Laboratories.

Permission for review of the hospital record of the patient in case 1 was granted by Capt. G. B. Taylor (MC), U. S. N., Commanding, the Bethesda Naval Hospital; and permission for review of records and other material in case 2 was granted by the Director, Prince Georges General Hospital, Cheverley, Md., and by Dr. Russell S. Fisher, Maryland State Medical Examiner, Baltimore.

2. (*a*) Wood, F. C.: Poisoning by Nitric Oxid Fumes, Arch. Int. Med. **10:** 478 (Dec.) 1912. (*b*) von Oettingen.[1]

3. Flury, F.: Die Rolle des Stickstoffmonoxyds bei der Vergiftung durch Nitrose Gase, Arch. exper. Path. u. Pharmakol. **157:** 104, 1930.

This variation in the clinical picture may be best accounted for by the composition of the fumes. When the content of nitric oxide is high (in sources of "nitrous fumes," other than nitric acid, as for example in arc welding [4]), there are cerebral symptoms, whereas, when the content of nitrogen dioxide is high (as in nitric acid), there are irritant phenomena.[3] In the acute stage hemoconcentration and thrombocytosis may be observed. If there is a significant concentration of nitric oxide, methemoglobinemia may be found. Patients surviving pulmonary edema may develop bronchopneumonia, and purulent bronchitis may be a recurrent problem for several months. Late complications of this type may well be responsible for fatal cases that go unrecognized as being related to the initial injury.[5] A rare late complication is bronchiolitis obliterans, in which the main clinical features are cyanosis and dyspnea with a chest x-ray picture simulating that seen in miliary tuberculosis.[6]

Two cases of exposure in one accident are described here, illustrating burn and fume injury by nitric acid. The accident occurred Dec. 29, 1953, in a large top-floor laboratory where research utilizing red fuming nitric acid had been in progress for some time. The personnel involved had considerable experience in its handling, and the person directly involved in the explosion had done the task several times before the accident. About 6 liters of red fuming nitric acid was distributed in contact with strips of titanium metal among 24 Erlenmeyer-type glass flasks equipped with glass stopcocks for venting. The tray holding the flasks was in a conventional, ventilated wall-type laboratory hood. The laboratory was 90 by 40 by 10 ft. A chemist was venting a flask containing 250 cc. of red fuming nitric acid and strips of titanium when it exploded, starting a chain explosion of the other flasks.

REPORT OF CASES

CASE 1.—A 28-year-old chemist was showered with liquid acid of uncertain but probably high temperature. He was wearing rubber gloves and a jacket. As the room was filling with dense "nitrous fumes," fellow workers rushed to his aid and within seconds played running water on him with a hose. It was already apparent to his co-workers that his face was burned, the skin appearing chalky-yellow. Eighteen minutes after the explosion he was taken to a local hospital, where his eyes and ears were covered with a saturated solution of sodium bicarbonate and facial and body burns dressed with petrolatum gauze. He received penicillin, morphine sulfate, and fluids intravenously. For the first two days, he experienced nausea and vomiting. On the third day, he was transferred to the Bethesda Naval Hospital. On admission, his temperature was 103 F, pulse 136 per minute, and respirations 24 per minute. There were first and second degree burns of the entire face and of the nasal canal and third degree burns of the forehead and ears. The right cornea was semiopaque throughout, the left appearing similar but less severely burned. There were second degree burns of the upper neck; small scattered second degree burns of the chest; second degree burns in the right axilla; first and second degree burns of the abdomen; first and second degree burns of the penis and scrotum; scattered third degree burns of the dorsum of the hands, fingers, and radial aspect of the right hand and forearm; third degree burns of the medial aspect of the right arm and forearm; second and third degree burns of the left forearm; and third degree burns of the anterior aspect of the right thigh. On admission, the patient's chest was clear to percussion and auscultation, but he shortly developed severe dyspnea, the respiratory rate varying from 40 to 70 per minute. This was partly explained on the basis of pulmonary edema, but with the appearance of mediastinal and subcutaneous emphysema it was apparent that there was a rupture of the tracheobronchial tree at some point. Signs of respiratory obstruction appeared, and on the second hospital day a tracheotomy was performed, with marked decrease in the degree of cyanosis and improvement in respiratory effort. Considerable thick mucus and frothy edema fluid was suctioned from the trachea. A portable x-ray film of the chest revealed marked densities of edema scattered throughout both lung fields and the presence of mediastinal air. He was given oxygen and Alevaire (a mixture of 0.125% Superinone [oxyethylated tertiary octylphenol-formaldehyde polymer], 5% glycerin, 2% sodium bicarbonate, and water) and fluids intravenously in amounts sufficient only to maintain urine output. His condition remained very poor throughout the second hospital day, with cyanosis, rapid pulse, and rapid, shallow respiration. On the third day, however, his condition stabilized in an oxygen tent with Alevaire. He was given 100 cc. of serum albumin and took fluids orally. By the end of the third day, he was markedly improved. On the fourth day, he received 500 cc. of whole blood. A posteroanterior film of the chest on the sixth day was essentially normal. The mediastinal emphysema was resolved. The hospital course was then one of general improvement. His temperature, which varied from 101 to 103 F during the earlier stages, returned to normal by the ninth day. The right cornea, which had been semiopaque throughout, was clear by the 28th day, but the left cornea had become opaque. Skin grafting of the sites of third degree burns was begun on the 27th day. At the time this case was reviewed, two and one-half months after the accident, the patient was doing well, remaining hospitalized for various plastic procedures.

CASE 2.—A 38-year-old chemist was one of those who came to aid the patient in case 1 seconds after the accident. There is little information about early symptoms, other than that he is said to have had a cough after the accident and had tightness in the chest the first few days. He took sick leave, unusual for him, but complained of no symptoms other than cough, until Jan. 19, 1954. The cough increased in severity, and he experienced chilly sensations with fever. He consulted a physician for the first time Jan. 21, 1954 (21 days after exposure), who found only loud rhonchi on examination of the chest. His symptoms became rapidly and progressively more marked; he developed retrosternal pain, a feeling of tightness in the chest, and later shortness of breath. Treatment with chlortetracycline (Aureomycin) was begun Jan. 23, 1954. The following day shortness of breath was so severe the patient had to remain seated.

On admission to the hospital, Jan. 24, 1954, he had a dry hacking cough, marked dyspnea showing severe respiratory effort, and a respiratory rate of 52 per minute. Temperature was 104 F, pulse 128 per minute, and blood pressure 170/90 mm. Hg. Abnormal findings, limited to the chest, were wheezing, sonorous breath sounds, and rales throughout. Urine was normal, the red blood cell count was 4,050,000 per cubic millimeter, white blood count 11,100 per cubic millimeter, hemoglobin 13.1 gm. per 100 cc. The white cell differential count was polymorphonuclear leukocytes 81%, lymphocytes 14%, stab forms 3%, and eosinophils 2%. A posteroanterior chest film on admission revealed small, irregular densities, 1 to 2 mm. in diameter, diffusely scattered throughout the lung fields. These miliary-like densities had indistinct, irregular margins and were of uniform radiopacity. There was a closer relation to bronchial markings than to vascular ones. The patient was given chlortetracycline and dextrose and saline intravenously. His temperature fell to 99.4 F, and he remained afebrile. The hospital course was one of rapid deterioration. Cyanosis of the mucous membranes and nailbeds was noted and progressively deepened. Respirations gradually became shallow, the blood pressure fell, and the patient died Jan. 25, 1954, approximately 30 hours after admission. An autopsy was performed, which revealed bronchiolitis obliterans and acute pulmonary edema. The details of this case are the subject of another report.[6]

Five co-workers, involved in the rescue of the patient in case 1, were interviewed for any possible symptoms.

[6] McAdams, A. J., Jr.: Bronchiolitis Obliterans, Am. J. Med., to be published.

All experienced some coughing while in the room, and three continued to have some cough for one to three days. Three had chest pain. One had difficulty in sleeping the second night after the accident, awakening with rapid respiration, a sensation of rumbling in the chest, and a deep desire to cough that he suppressed. One had nausea while exposed, and one had lacrimation. All had normal chest x-rays two weeks later.

COMMENT

The extreme rapidity with which serious and even fatal injury may be sustained by contact with liquid concentrated nitric acid or with its fumes makes it mandatory that prevention be emphasized. The cases described in this report illustrate the two types of injury by concentrated nitric acid; injury at the site of contact (in this case skin and eye) with the (liquid) acid, and pulmonary injury from inhalation of the "nitrous fumes" (the oxides of nitrogen). These cases are noteworthy in emphasizing the extremely hazardous nature of the material in that both patients were experienced chemists. Granted that, in these circumstances, the behavior of the acid was totally unexpected by these workers, the rapidity with which injury occurred despite quick action by all should promote greater efforts at prevention.

There has been considerable disagreement on an allowable concentration for safe exposure to the fumes. This ay in part be due to a failure to consider the composition f the oxides making up the fumes. Nitric oxide is primarily a cerebral depressant and also forms methemoglobin on contact with blood. Although it is oxidized rather rapidly to nitrogen dioxide on contact with air, if the initial concentration is high, symptoms will be pri- rily cerebral. If concentration of nitrogen dioxide is sole consideration, it is probable that 5 ppm is the maximum allowable concentration for chronic exposure.[7]

All possible foolproof safety devices for storage and transfer should be utilized in large-scale laboratory or industrial operations. Personal protective apparel should include eye protection as part of a hood system to cover the head, neck, and arms. Long-sleeved gloves should also be used. All apparel should be fabricated of nitric acid-resistant material. Breakage of carboys or other containers most frequently causes the accidents with serious results.[1] The chemical should not be handled or stored except where adequate ventilation exists or where provision for quick clearing of fumes has been made. If handling and storage is in a poorly ventilated area, or where quick clearing of fumes from the atmosphere cannot be accomplished, workers should wear self-contained oxygen breathing equipment during all operations. Above all, no one should handle concentrated nitric acid or enter a storage area alone. The companion's dual duty should be the enforcement of safety precautions and the prompt execution of first aid in the event of accident. Water in adequate amounts must be within a few seconds' reach of all who handle this material. This should be in the form of showers, immersion tanks, and the like for immediate washing of any part of the body, including the eyes. Application of dilute (1 to 5%) sodium bicarbonate solution may follow thorough washing.[8]

Since there can be no control of the nature of the fume composition in an accident of the sort described here and since no information on fume concentration in the atmosphere was obtained, it must be assumed that any or all types of systemic injury have been sustained by any given patient. Treatment is nonspecific and hence difficult and on the whole unsatisfactory. In the case of burns, after the initial decontamination, the injury should be handled as one would thermal burns. It should be noted that caustic injuries by nitric acid heal slowly. In the case of inhalation of fumes, the patient should be closely observed even though there appear to be no early signs of injury. The onset of pulmonary edema may be considerably delayed and insidious in development. Where there is any evidence of pulmonary damage, an antibiotic should be administered. The period of observation should be sufficiently long to exclude the development of late complications, which may mean a follow-up period of several weeks. Of first importance in evaluating the patient are serial roentgenographic examinations. Several reports have described the x-ray changes in the lungs after inhalation of oxides of nitrogen fumes.[9] This procedure is of particular importance in detecting the development of bronchiolitis obliterans, as in our case 2. Although this is a rare complication, some consideration should be given to its possible detection in the early stages and of its treatment. The development of bronchiolitis obliterans following pulmonary injury may occur within 14 days.[10] In one report of a patient exposed to "nitrous fumes" seven days prior to death, evidence of beginning organization was noted.[2a] In experimental animals exposed to various war gases, Winternitz [11] found organization as early as four days after exposure. In a patient showing small densities distributed diffusely throughout the lung fields in the roentgenogram, persisting longer than one week, the development of this disease should be strongly suspected.[6] As yet, no form of therapy has resulted in improvement when the clinical picture of bronchiolitis obliterans is complete. If, however, the potential victim is detected early, it seems reasonable to expect that a fatal outcome may be averted. It is apparent that suppression of the granulating process must be accomplished, and it is proposed that to this end corticotropin be utilized as well as some form of antibiotic regimen. Administration of fluids parenterally should be done cautiously in the expectation of pulmonary edema.

SUMMARY

Red fuming nitric acid is a dangerous material to handle and may cause serious injury by direct contact or through inhalation of its fumes. In one of two cases representing various features of injury due to red fuming nitric acid, there were serious acid burns of the body, damage to the cornea, and acute pulmonary edema. The other case ended fatally due to bronchiolitis obliterans.

VENTRICULAR ARRHYTHMIA INDUCED BY METHOXAMINE HYDROCHLORIDE

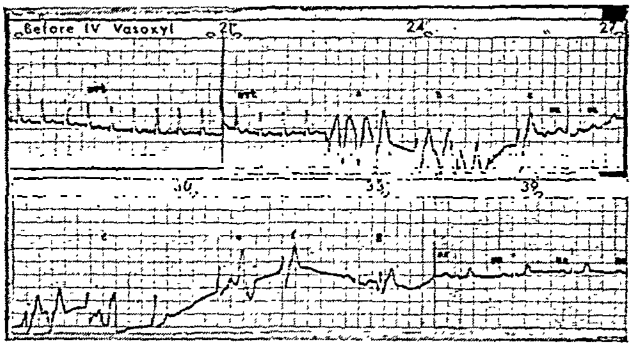
Capt. Walter E. Shector (MC), U. S. A. F.
John T. McLaughlin, M.D.
and
Charles Dowling, M.D., Inglewood, Calif.

Methoxamine (Vasoxyl) hydrochloride is a synthetic sympathomimetic compound whose chief therapeutic use has been in the prevention of hypotension induced by spinal anesthesia.[1] Recent reports in the literature, however, have suggested that methoxamine hydrochloride is effective in terminating attacks of supraventricular tachycardia.[2] Chotkowski and co-workers [2b] have commented upon the dramatic reversion of the paroxysmal to the normal rhythm in a matter of seconds when the drug is administered intravenously, and Berger and Rackliffe [2a] state that methoxamine hydrochloride is perhaps unique among pressor amines in that it does not cause cardiac irritability. Stutzman and co-workers [3] noted that, of some 26 sympathomimetic compounds tested, only methoxamine hydrochloride and phenylephrine [4] (Neo-Synephrine) hydrochloride did not induce ventricular fibrillation in the experimental animal during cyclopropane anesthesia. Nathanson and Miller,[2c] however, noted ectopic ventricular activity after the administration of phenylephrine hydrochloride in a patient with shock following coronary occlusion, and, in a second patient with acute myocardial infarction, a supraventricular tachycardia treated with intravenously given phenylephrine hydrochloride was followed by ventricular tachycardia. One of us (W. E. S.) worked under the late Dr. M. Nathanson and so was able to see, at first hand, some of the patients with supraventricular tachycardia treated with methoxamine hydrochloride by this physician. No significant untoward effects were noted until recently, when a patient with supraventricular tachycardia developed ectopic ventricular activity following the intravenous administration of 10 mg. of methoxamine hydrochloride.

REPORT OF A CASE

A 35-year-old white male was seen in the office on the afternoon of July 27, 1954. After lunch that same day, the patient had returned to work when he noted the sudden onset of rapid, regular, forceful heartbeats. Because the rapid heart action persisted, he came to the office about one-half hour later. The only abnormal finding on physical examination was a rapid but regular heart rate of 160 beats per minute. An electrocardiogram revealed supraventricular tachycardia.

During the administration of all therapy, a continuous tracing of lead 2 was taken. Mechanical reflex stimulation of the vagus nerve was attempted without modification of the arrhythmia. After these procedures 10 mg. of methoxamine hydrochloride was given rapidly, intravenously. It may be noted from the electrocardiogram that, approximately 22 seconds after the administration of methoxamine hydrochloride, ectopic complexes, suggestive of ventricular tachycardia, made their appearance (a, b of figure). After an additional 4 seconds, apparent sinus rhythm was noted for two successive beats (sa of figure) and then multifocal ventricular complexes made their appearance (c, d, e, f, g of figure). Finally, maintained sinus rhythm of 70 beats per minute was noted, approximately 34 seconds after intravenous medication had been given. (Two unifocal premature ventricular complexes were noted during the next minute of the tracing, i. e., immediately after the restoration of maintained sinus rhythm.) The patient was subsequently hospitalized for medical examination. The patient at this time stated that he had experienced three attacks of rheumatic fever, at ages 7, 14, and 18 respectively. In addition, two other attacks of paroxysmal heart action had been experienced three and one years previously. The first attack was aborted after several hours by intramuscularly given sedatives and the second attack aborted spontaneously after a few minutes. Physical examination revealed a grade 2 to 3 systolic and diastolic murmur along the left border of the sternum and a grade 2 systolic murmur at the mitral area. Complete blood cell count, erythrocyte sedimentation rate, and blood iodine level were within normal limits. The temperature chart was unremarkable over a period of several weeks. Cardiac fluoroscopy confirmed the presence of aortic and mitral valvular disease.



Electrocardiographic recordings before and beginning 21 seconds after intravenous administration of methoxamine (Vasoxyl) hydrochloride in patient with supraventricular tachycardia: a, b, c, d, e, f, g—ectopic ventricular complexes; sa—auricular contraction arising from sinoatrial node; svt—supraventricular tachycardia with a ventricular rate of 160 beats per minute.

COMMENT

Methoxamine hydrochloride is able to induce rapid reversion of supraventricular tachycardia to sinus rhythm by apparent reflex vagal stimulation. This reflex is activated because of the rapid rise of blood pressure that stimulates the carotid sinus and other pressor receptors in the aortic arch. The safety of this drug has been pointed out by several authors,[5] although Chotkowski [2b] noted that, in all of his patients with supraventricular tachycardia, ectopic ventricular complexes appeared at the onset of rhythm reversion. One of this same author's patients, moreover, developed atrial fibrillation of about 40 seconds' duration during reversion.

Contrary to the experiences of the above-noted clinicians, we have recently observed an adverse complication during intravenous therapy with methoxamine hydrochloride that we feel is of a more serious nature than has heretofore been reported. In our patient, recurrent ectopic ventricular activity appeared in a temporal relationship that strongly points to methoxamine hydro-

induced by moving a gallstone in one instance (case 1 of the table) and by tracheal suction in the presence of prolonged tachycardia in the other (case 6 of the table) seemed to be precipitating factors. Administration of a large dose of tetracaine (Pontocaine) glucose solution (16 mg.) in the cerebrospinal fluid while preparing a 299 lb. (135.6 kg.) patient for a radical (Wertheim) hysterectomy for carcinoma of the cervix (case 4 of the table) was immediately followed by syncope. Cessation of respiration occurred, and the heart was observed to stop beating. It started at once with massage. Whether the third case was precipitated by bronchial biopsy or by hemorrhage is undetermined. The biopsy was followed immediately both by cardiac standstill and by hemorrhage. The heart started promptly after massage while the hilus of the lower lobe from which the blood had gushed was held compressed by the other hand. After reestablishment of cardiac function, a lobectomy was done, and the patient recovered uneventfully. In addition, a patient is cited who had bled to death from ulcer erosion of the gastroduodenal artery. The heart had stopped beating. With four transfusions running simultaneously, the gastroduodenal artery opening was plugged by manual pressure and the heart massaged. It was restarted and kept going for two and one-half hours by almost constant massage. Death then occurred. This case, however, is not one of cardiac arrest as under discussion here but rather an example of death from hemorrhage, and it shows only that it is possible to restart the heart of a recently exsanguinated person. This heart would not respond to external electric stimulation (Pacemaker)[7] either before or after massage. The six cases of cardiac arrest occurred in various places, as shown in the table.

Data on Six Cases of Cardiac Arrest

Case No.	Disease	Age, Yr.	Preceding Event or Procedure	Cause of Arrest	Where Arrest Occurred	Time from Arrest to Massage	Result
1	Cholelithiasis	39	Cholecystectomy	Reflex	Operating room	10 min.	Died in 2 wk.; decerebration
2	Carcinoma of larynx	65	Preoperative narcotic	Anoxia	On ward, preoperatively	20 min.	Died in 72 hr.; decerebration
3	Bronchiectasis with hemorrhage	59	Bronchoscopic biopsy	Biopsy; hemorrhage	Endoscopy room	2 min.	Recovery
4	Carcinoma of cervix; obesity (299 lb. [135.6 kg.])	70	Spinal anesthesia	Overdose	Anesthesia induction room	4 min.	Recovery
5	Perforated duodenal ulcer 2 hr. postoperatively	35	Receded jaw in sleep	Anoxia	On ward, postoperatively	17 min.	Died in 6 hr.; decerebration
6	Patent ductus arteriosus	11	Ductus exposure; tracheal suction	Tachycardia; reflex	Operating room	10 sec.	Recovery

PROMPTNESS

Naturally, one wishes to be certain that cardiac arrest has occurred before making an incision into the chest, but sudden blanching, with disappearance of pulse, absence of blood pressure, and dilatation of the pupils, may be taken as almost infallible signs of cardiac arrest. In such a situation, opening of the left side of the thorax immediately for heart massage will so seldom prove erroneous that those instances may properly be counted as judicious diagnostic procedures. The prick of a needle will sometimes start a heart that has stopped from reflex phenomena and should be tried first. A heart impulse stimulator may be used if desired. The form I use is the Cardiac Pacemaker, manufactured by the Electrodyne Company, Norwood, Mass. According to Zoll,[8] "it must be applied promptly while the heart is still responsive, and adequate pressure must be restored with the use of accessory agents like Nor-epinephrine. Therefore, if desired, try the Pacemaker promptly, but do not delay other measures by more than a minute. If unsuccessful, open the chest and massage the heart without delay."

TECHNIQUE OF MASSAGE AND CARDIAC RESUSCITATION

The left side of the thorax should be opened immediately. Only a knife is required. Fifteen seconds is all the time needed. Asepsis and antisepsis should be disregarded unless proper measures can be immediately instituted. The hand and wrist should be introduced between the ribs and the heart flicked with the finger. This will sometimes start it if a vagovagal reflex has been the cause. If not, the heart should be squeezed and allowed to dilate once or twice. If this does not start it, it should be compressed at the rate of 60 to 70 times a minute. By use of a knife in the opposite hand, the cartilages should be divided above and below the intercostal space entered, which should be the fourth, but may be the fifth. The patient should at once be put into Trendelenburg position. If an endotracheal tube is not already in place, one should be inserted promptly; hyperoxygenation should be induced and artificial respiration given through the anesthesia bag. The heart cannot be restarted and the brain connot be saved without an abundance of oxygen. Adequate ventilation must be provided, which means a clear airway and excessive oxygen. There is not enough oxygen or enough circulation unless the myocardium can be made pink by massage. Proper pressure must be maintained if there is to be hope for survival. This may be possible by massage alone. Levarterenol (Nor-epinephrine) sometimes suffices in addition to massage, but arterial transfusions may be required. If the heart is in standstill and cannot be started by massage alone, phenylephrine (Neo-Synephrine) hydrochloride has a place if used in very small amounts. We have used 0.5 cc. of 1: 1,000 phenylephrine in 9.5 cc. of 1% procaine. Gross[9] uses and recommends 50% glucose injected directly into the heart chambers. He also has used calcium chloride for stimulatory effect upon the myocardium.

Phenylephrine and epinephrine are contraindicated in the hyperirritable situation of ventricular fibrillation. Except for the occasional spontaneous conversion of ventricular fibrillation to normal rhythm, the fibrillating heart must be brought to standstill before normal rhythm can be reestablished. Procaine and procaine amide have recently been used for this purpose. Procaine causes a rise in the heart rate, ventricular extrasystoles, and a fall in blood pressure, according to Humphreys and associates.[10] They think that tachycardia may be caused rather than prevented by procaine. From the time of the Mautz [11] demonstration that procaine is a myocardial depressant, however, many others have believed procaine to be excellent. In the presence of ventricular fibrillation, procaine injected into a ventricle, and possibly the right is the better one, does seem to have a paralytic effect. Procaine and procaine amide probably should be tried in any case of ventricular fibrillation in which defibrillation is not immediately accomplished by other methods.

As first pointed out by Wiggers [2] and frequently reemphasized since, the myocardium must be oxygenated before defibrillation can be accomplished by any means. Electric shock is probably the most reliable of the methods, when a superabundance of oxygen is maintained. Lampson, Schaeffer, and Lincoln [12] reported a case in which ventricular fibrillation lasted for 27 minutes with survival by massage, which Beck [5] cites as the only recorded human case of ventricular fibrillation converted without electric shock. For defibrillation by electric shock, a current of from 1.5 to 2 amp. is necessary. At least 110 volts may be required, and, for a very large heart, Johnson and Kirby [13] are prepared to use as high as 270 volts. The time of application should not be over one-tenth of a second lest the heart be burned. The patient's entire body must be made to contract and almost to rise off the table before voltage can be assumed to be adequate for defibrillation. The defibrillating electrodes are applied to opposite sides of the heart either through or within the pericardium. Three or four shocks should be applied in rapid succession. There are numerous fairly simple electrical defibrillators now available on the market. All must meet the requirements outlined above.

CAUSES

Reflex Phenomena.—Vagovagal reflexes have been widely discussed. It is known that stimulation of the vagus nerves may depress the cardiac beat stimulus that usually rises in the auricle. Unless the specific tissue in the ventricles, in which there are no vagal nerve endings,[14] takes over, there will be no impulse and the situation of cardiac arrest will have ensued. If the specific tissue takes over in the multiple foci instead of from a single focus, fibrillation of the ventricles results. The fact that the vagus nerve may be stimulated in a wide variety of ways (vascular stretching, mucosal pressure, and serous lining irritation) explains the multiplicity of causes that have been reported as responsible for instigating cardiac arrest. These include: (1) traction on a mesentery or occurrence of a pulmonary embolus; (2) spraying of the throat; (3) insertion of an endoscopic instrument, moving of an endotracheal tube, or clamping of a bronchus; and (4) thoracentesis or incision into the pleura or pericardium.

Anoxia.—Anoxia sets the stage for development of arrest or ventricular fibrillation. Anoxia not only weakens the contractile ability of the heart muscles but also potentiates the depressant effects of any anesthetic agent being exhibited and thus decreases the ability of the ventricles to respond effectively to self-induced stimuli when auricular stimulus has been lost by vagal excitation (vagovagal reflex). Although anoxia is not in itself known to cause a vagovagal reflex, it is unquestionably, from a clinical standpoint, the most likely of all complications to cause cardiac arrest. The most common cause of anoxia is mechanical blockage of an airway in one way or another.

Anesthesia.—The deeply overanesthetized patient with hypoxia, as everyone now realizes, is in danger of death from gradual weakening of the heart to flabby dilatation and cessation. The lightly or underanesthetized, cyanotic patient is equally in danger of arrest from vagovagal reflexes following manipulative procedures of any sort during the time such conditions exist. Of oxygen one cannot get too much. Of drugs, the fewer the kinds at one time the better. Of anesthesia one needs not too little and not too much, but just enough. The basic causes of sudden cessation of heartbeat or sudden onset of ventricular fibrillation, therefore, seem to be: (1) reflexes presumably mediated through the vagus nerve to the heart; (2) anoxia, most often from mechanical blockage of an airway; and (3) anesthesia, either too much or too many kinds.

PREVENTION

No guarantee can be offered by any physician that any patient may not fall victim to the complication of cardiac arrest; however, there are some important preventive measures to be kept constantly in mind. If preliminary drugs are limited, if atropine or scopolamine is always exhibited, if oxygen is supplied in superabundance, if depth of anesthesia is kept as light as is consistent with surgical requirements, the patient then is in a state of optimum preparation for major surgery. Patients with obstructive lesions like carcinoma of the larynx must not be drugged before they are in the operating room or constantly attended, lest they suffocate. Light anesthesia, a vagus undepressed by suitable blocking agents, such as atropine centrally or procaine peripherally, allow transmission of harmful impulses along the vagus to the auricles. A myocardium made weak or irritable by anoxia, too much anesthesia, or debilitating illness with nutritional deficiency such as vitamin B complex may suddenly fail to form a beat at all or go into ventricular fibrillation. Acetylcholine is the mediator of vagal nerve action. Atropine and also scopolamine block this action.

SUMMARY AND CONCLUSIONS

If the figures and data from these five cases of cardiac standstill and one case of ventricular fibrillation were in thousands instead of units, they would be more impressive perhaps, but I doubt if the following lessons brought induced by moving a gallstone in one instance (case 1 of the table) and by tracheal suction in the presence of prolonged tachycardia in the other (case 6 of the table) seemed to be precipitating factors. Administration of a large dose of tetracaine (Pontocaine) glucose solution (16 mg.) in the cerebrospinal fluid while preparing a 299 lb. (135.6 kg.) patient for a radical (Wertheim) hysterectomy for carcinoma of the cervix (case 4 of the table) was immediately followed by syncope. out by the cases would be any more valid. 1. All of these six abruptly arrested hearts were restarted. 2. The two patients in whom anoxia was the primary cause of cardiac arrest died. 3. Each of the three patients in whom effective massage was established within four minutes recovered with brain function intact. 4. Every one of the three patients in whom appreciable delay occurred became decerebrated although cardiac function was restored. 5. Cardiac arrest occurred elsewhere than in the surgical pavillion in two cases and at other times than during operation in four of the six cases. 6. Ventricular fibrillation must be treated actively as long as there is evidence of viability, fully normal recovery having been demonstrated after one hour and 50 minutes of artificially maintained cerebral and cardiac circulation. 7. The common causes of cardiac arrest are recognizable and definable and largely preventable. Full application of knowledge currently available regarding prevention would almost eliminate the complication, except in cardiac surgery itself.

CHEMICAL LABORATORY

XANTHINES, TANNINS, AND SODIUM IN COFFEE, TEA, AND COCOA

Robert G. Martinek, Pharm.D.
and
Walter Wolman, Ph.D.

The recent advent on the market of new types of preparations of coffee, tea, and cocoa has created an interest in the xanthine, tannin, and sodium content of these new types as compared with the older accepted forms. This report was prepared because of requests received by the Chemical Laboratory of the American Medical Association for this type of information. The xanthines include such substances as caffeine, theophylline, and theobromine. Tannins are complex materials with a high molecular weight that are formed from phenolic substances such as pyrogallol, pyrocatechol, phloroglucinol, and gallic acid, and these frequently are esterified with sugars. The tannins are recognized as protein and alkaloid precipitants. Differences between the various types of preparations are in most instances the result of the preliminary treatment given to the product by the grower or packager.

Instant coffee is prepared by extracting ground roasted coffee ith water. The powdered soluble coffee remains after evapora- of the water from this extract. Decaffeinated coffees are nerally prepared by steaming the green beans under pressure to soften them and by dissolving and extracting the caffeine with such organic solvents as benzene, chloroform, or alcohol. The residual solvent in the bean is then removed by resteaming before the roasting process. As yet it has not been possible to extract all the caffeine in commercially prepared coffee. During the roasting process, previously colorless tannins in the coffee bean are oxidized to colored products.

Teas are classified into two general classes, black tea and green tea. The differences arise from the treatment applied to the leaf. Black tea is a fermented product. The fermentation process (oxidation) reduces the astringency of the leaf and changes the color, aroma, flavor, strength, and body of its liquor. Upon fermentation of the tea the colorless tannins turn red or brown, which gives the tea its characteristic color. Green tea is a preparation in which the fermentation process has been arrested by steaming the green leaf and then drying it. The tannins in green teas are in their colorless state, and the lack of formation of the red or brown tannins is considered one measure of a good green tea. Of the xanthines in tea, theobromine and theophylline are present only in trace amounts. The predominant xanthine is caffeine.

The partially fermented cacao bean is the source of chocolate and cocoa. As defined by Webster, chocolate is "the solid or pliable mass obtained by grinding roasted cacao beans which have been freed from germ and shell"; cocoa is "chocolate deprived of a portion of its fat and pulverized." Theobromine is the predominant xanthine in cocoa. During fermentation the tannins are oxidized by oxidase enzymes to form a red coloring matter.

The accompanying tables give the percentage of certain xanthines, tannins, and sodium in several market preparations and the amounts present in a cup of the beverage. The methods of analysis were gravimetric[1] for caffeine, titrimetric[2] for tannins, and flame photometric[3] for sodium. The average values reported are based on duplicate determinations of single samples of material. Differences in the amount of the contents of different brands cannot be considered of significance because not enough samples were studied to establish statistically significant variations. The reported values were determined for the equivalent of a cup of beverage prepared according to the directions given on the label of each product; however, many users of these beverages do not follow label directions and prepare the beverages according to personal preference. Therefore, in most instances complete extraction of the sample was effected in order to determine the maximum quantity of the constituent potentially available. In some cases, contact between the solid and the water was limited to the time for preparation as stated on the label in order to check the amounts of the constituents obtained if the label directions were strictly followed. By this means, direct comparisons of the cups of beverages prepared from the various types of products were made.

The amount of caffeine in each of the several brands of the regular ground bean coffee is about the same (table 1). Tests with brand A indicate that the method of preparing a cup of coffee has little significant effect on the amount of caffeine extracted; extraction of the caffeine by any of the methods of preparation is virtually complete. Almost twice the amount of caffeine per cup can be obtained from the regular ground bean coffee as from the regular instant coffee; in contrast, the tannin content is somewhat higher in the instant type. Caffeine content per cup prepared from the regular ground coffee bean is roughly three times that of the regular decaffeinated coffee and about four to eight times that of instant decaffeinated coffee. Tannin content of the regular ground bean is slightly less than that of decaffeinated coffee. Advertising that makes claims implying the almost total removal of caffeine in decaffeinated coffees must be viewed with skepticism.

The potential caffeine content per cup prepared from bulk black tea is comparable to that from regular ground bean coffee, although, if prepared according to the label, about 65% of the leaf's caffeine is extracted (table 2). There is about three-quarters the amount of caffeine in green tea as in black tea. In general, the tannin content of tea is roughly four times that of coffee. The lower amounts of caffeine and tannins per cup obtained with tea bags are simply the result of the smaller amounts of tea used in each bag, as compared with the amounts recommended for use on the label of the bulk teas. Analyses indicate that there is over twice as much xanthine (theobromine) present in a cup of cocoa (table 3) as there is xanthine (caffeine) in coffee or tea.

A few sodium determinations were done on representative samples of the several types of beverages. These beverages were prepared according to the label instructions. The results indicate that there is about 0.30 to 0.35 mEq. of sodium per cup of coffee and about one-half that amount in tea. About the same amount of sodium is contained in a cup of cocoa as in a cup of coffee; however, over three times the amount of sodium is present in a cocoa produced by the Dutch process (a process in which cocoa is treated with alkali). For the sodium determinations the beverages were prepared with distilled water in order that the measurements would not reflect the sodium content of tap water, which varies with the locality. In calculating the amount of sodium imbibed by patients in drinking a cup of beverage, it is necessary for the physician to take into consideration the amount of sodium in a cup of the local water supply as well as that supplied by the material used for preparing the beverage.

SPECIAL MESSAGE FROM THE BOARD OF TRUSTEES—

NATIONAL COMPULSORY DISABILITY BENEFITS

The House Ways and Means Committee, without any public hearings, has reported H. R. 7225 to amend the Social Security Act. One proposed amendment is of vital concern to the medical profession because of its potential implications: an amendment to provide cash benefits to certain Social Security beneficiaries who are permanently and totally disabled. In effect, this proposal would establish, for the first time in this country, a system of national compulsory disability "insurance" under Title II of the Social Security Act. This title is the one under which the Old-Age and Survivors Insurance program is conducted.

Because of the piecemeal approach to the socialization of medicine, of which this proposal is the keystone, the medical profession and the nation as a whole have not been as alert to the danger as they were during the 1949-1950 campaign against the Truman-sponsored compulsory health insurance bills. The present danger, in fact, is greater. If this bill is adopted it can be confidently predicted that the cash disability benefits will gradually be extended to the temporarily disabled and that eventually the federal government will initiate a system of compulsory health insurance as a necessary counterpart to the cash benefits program. This combination of national compulsory health insurance and national disability benefits has been true in almost every other nation where government disability benefits exist. The combination becomes inevitable because the government must control the treatment of the disabled if it is to maintain any control over the extent of the cash benefits. In fact, the present bill requires concurrent rehabilitation for the permanently and totally disabled on which the cash benefits will be contingent.

The Social Security Act as adopted in 1935 and as later amended was dedicated primarily to the promotion of government-provided minimum economic security for older retired workers and their survivors. The extension of the act to involve disability was contemplated by many of its proponents from its inception, but not until the Social Security amendments of 1954 was a disability benefit included under OASI. The "waiver of premium" or "disability freeze" provision was enacted at that time whereby certain periods of permanent and total disability were excluded in the computation of benefits under Title II of the act for potential Social Security beneficiaries. With the enactment of this provision, physicians for the first time were brought into the operation of the act, in that their services were required to identify the disabled beneficiaries. The move to extend the "freeze" to include a cash benefit was predicted then and has now become a reality.

On the date of the preparation of this statement, we were exerting every effort to persuade the House of Representatives not to adopt this far-reaching change in the Social Security Act, although we were aware of the fact that our efforts would probably be fruitless. This awareness stemmed from our knowledge that previous proposals to expand the Social Security Act had met with almost unanimous bipartisan political support. Furthermore, the parliamentary situation in the House of Representatives was such that consideration of the bill was limited to 40 minutes of debate and no opportunity to amend.

It is unlikely that this bill will be considered by the Senate at this session of the Congress. When it is considered in the second session, public hearings will probably be held. The profession, therefore, has time to become thoroughly aware of the true nature of this bill and its effect on health insurance and medical practice and to take active steps to develop a public climate that will permit the members of the Senate to vote against it.

During the next several months THE JOURNAL will publish a series of articles on existing state and foreign governmental programs for the provision of cash benefits to the disabled. It is urgent that every physician, if he wishes to exert his full influence in the maintenance of the free practice of medicine, become thoroughly cognizant of the economic impact of these programs.

The distance between our present medical freedom and complete government regimentation has narrowed considerably. The remaining gap will be closed completely unless physicians throughout the nation take constructive action to educate themselves, the public, and their congressmen and senators during the next few months. On page 1036 of this issue of THE JOURNAL is a press release from Dr. Gunnar Gundersen, Chairman of the Board of Trustees, which is reprinted for the information of readers.

HEMORRHAGIC HAZARDS FROM MASSIVE SALICYLATE THERAPY

Ever since Link and his associates [1] asserted in 1943 that salicylates induced hypoprothrombinemia in rats, a condition preventable by an adequate amount of vitamin K in the diet, considerable experimental and clinical data, in part controversial, have been published with respect to the effects of salicylate therapy on prothrombin. A relation between salicylate therapy and hemorrhage has long been suspected. It is well known, for example, that acetylsalicylic acid may cause gastric bleeding, especially in sensitive persons. Recently, Hawk and his associates [2] reported a case of massive gastrointestinal hemorrhage following the ingestion of 1,400 grains (90.8 gm.) of acetylsalicylic acid over a three week period. In 1885 Balette [3] recognized the relationship between the ingestion of salicylates and uterine hemorrhage, and in 1890 Binz [4] described instances of excessive and prolonged menstrual flow in women receiving salicylic acid. Ever since, occasional reports have appeared pointing out the connection between uterine hemorrhage and salicylate therapy.

Nearly all investigators agree that the salicylates prolong prothrombin time, which indicates a decrease in plasma prothrombin content. The effect on prothrombin content is rarely observed unless large doses of salicylates (more than 6 gm. per day) are ingested, as in the case of patients with acute rheumatic fever. Prothrombinopenia is fairly proportional to the plasma salicylate level up to 60 mg. per 100 cc., but it is rarely critical until higher salicylate levels are reached. These levels are seldom established during a course of salicylate therapy because of the pronounced salicylism that occurs. Although studies in animals suggest that the various salicylates are equally effective in prolonging prothrombin time, acetylsalicylic acid is considerably more potent in some instances. This effect is enhanced by fever and elevated metabolism. The prothrombinopenic action of salicylates is neither as pronounced nor as constant as that of bishydroxycoumarin and other related anticoagulant drugs.[5]

The precise mechanism of salicylate-induced hypoprothrombinemia is undetermined. Although conventional liver function tests presumably do not indicate damage to the hepatic parenchyma after the clinical use of salicylates, nevertheless it has been established that salicylates affect certain enzymatic processes in the liver. Moreover, it has been suggested that both salicylates and bishydroxycoumarin may block the utilization of vitamin K. Administration of vitamin K can overcome the depressant action of salicylates on prothrombin formation. Whether the use of large doses of salicylates in human beings results in frank hemorrhage is still subject to differences of opinion. While adequately studied cases of hemorrhage due to salicylate-induced hypoprothrombinemia appear in the literature, the phenomenon is probably infrequent. Very high plasma salicylate levels are required to reduce the plasma prothrombin content to the critically low level associated with bleeding.

To summarize: Goodman and Gilman maintain that the administration of salicylates in massive doses can appreciably lower the plasma prothrombin content, but only rarely to critical levels. The not infrequent hemorrhagic episodes observed in patients with acute rheumatic fever may be due, at least in some instances, to large doses of salicylates. In general, physicians should be cautious about prescribing massive salicylate therapy for patients with liver damage and with preexisting hypoprothrombinemia or vitamin K deficiency, as well as for patients in whom surgery is contemplated. Use of vitamin K on a prophylactic basis does not necessarily protect patients against hemorrhage, which may ensue as a result of a disease process or of an action of salicylates other than on prothrombin. Finally, salicylates should not be used concomitantly with bishydroxycoumarin.

POSTGRADUATE AND GRADUATE COURSES

In this issue of The Journal the first annual listing of Postgraduate and Graduate Courses for Physicians appears (pages 1052 to 1131). This listing is for the period September 1, 1955, to August 31, 1956, and has been prepared by the Council on Medical Education and Hospitals. It replaces the two semiannual lists published heretofore. As a result of the recently completed Survey of Postgraduate Medical Education, the new listing includes many more sponsoring institutions than in the past. The two categories of "graduate" and "postgraduate" courses are based on the definitions of these two phases of medical education adopted by the House of Delegates in December, 1952. In brief, graduate medical education is designed to prepare a physician for specialty practice or an advanced academic degree, whereas postgraduate education is designed to keep the physician abreast of his own field of practice or enlarge his knowledge of one specific aspect of it. Most graduate medical education is in the form of residency training, which is not included in this listing. With renewed interest in postgraduate education developing in the past few years, it is hoped that the listings here presented will help to encourage even greater use of postgraduate study by physicians.

ORGANIZATION SECTION

STATEMENT OF DR. EDWIN S. HAMILTON ON H. R. 9 AND H. R. 10 BEFORE COMMITTEE OF THE HOUSE OF REPRESENTATIVES

I am Dr. Edwin S. Hamilton of Kankakee, Illinois, where I am engaged in the active private practice of medicine. I am a member of the Board of Trustees of the American Medical Association.

I appear here today as a representative of that Association to support H. R. 9 and H. R. 10, 84th Congress, measures designed to provide tax deferment on retirement funds for self-employed persons and others not covered by pension plans. With me is Frank G. Dickinson, Ph.D., Director of the Bureau of Medical Economic Research of the Association. At the conclusion of my statement I should like Dr. Dickinson to discuss the technical aspects of these proposals.

At the outset I would like to state that the Americal Medical Association has, for a number of years, endorsed the principle of legislation of this type. We have collaborated closely with representatives of the American Bar Association, the original sponsors of this measure, and other national organizations of self-employed taxpayers who would be afforded some measure of tax equity by the enactment of these bills.

Early in 1948 our Board of Trustees was apprised of a movement then under way to promote enactment of federal legislation under which self-employed persons, including physicians, could provide their own retirement benefits through the deduction of amounts annually from their taxable income to finance retirement plans. The Board approved this movement, stipulating that there would be a reasonable limitation on retirement benefits for which such a provision could be made. This action was commended by our House of Delegates, the governing body of the Association, at its meeting in June, 1948.

In June, 1951, at the annual session of the American Medical Association, three resolutions reemphasizing our endorsement of this principle were adopted by the House of Delegates.

On May 13, 1952, representatives of the Association appeared before this Committee in general support of H. R. 4371 and H. R. 4373, 82nd Congress. At that time, we suggested various amendments to those bills. H. R. 9 and H. R. 10 now before your Committee include all of the basic amendments recommended by the Association in 1952.

In June, 1952, and again in December, 1952, our House of Delegates reiterated the endorsement of these proposals and recommended that each member of the Association give them his careful study and active support.

On Aug. 12, 1953, representatives of the Association again appeared before this Committee in support of H. R. 10 and H. R. 11, 83rd Congress.

It is the belief of the American Medical Association that physicians, dentists, veterinarians, lawyers, architects, merchants, and the many others who comprise the nation's self-employed have long been neglected in federal tax legislation relating to pensions. Under the existing law, corporations are entitled to set aside tax-free money to purchase pensions and annuities for their employees, and millions of employees are benefiting from that arrangement. Yet the self-employed are denied this tax advantage in providing for their old age. The purpose of these bills is to eliminate this discrimination and inequity. By extending the tax deferment privilege to the country's eleven million self-employed, and also to the millions of employees who are not covered by pension plans, this legislation will give them an increased incentive during their best earning years to save for their old age.

Unless something is done to make self-employment as financially attractive as the employee relationship, we believe there is a grave danger that many professional men will bypass the private practice of their profession. The trend today is definitely toward becoming an employed person. This situation also contributes to a maldistribution of physicians, since it makes the large city more attractive to the young professional man by providing more opportunities for him to become employed.

On the basis of my own observations over many years of practice in medicine, I am convinced that this is one of the factors contributing to the pronounced migration of professional people into urban areas. So, quite apart from the objective of obtaining tax equality with our employed counterparts, we urge you to approve legislation of this type, because it is in the public interest.

This legislation will be of particular benefit to physicians and other professional men who go through a long and costly period of training and whose earnings are bunched into a comparatively short period of years when they are subject to high income tax rates.

The need for such relief was demonstrated recently in the Kintner case, in which the status of physicians in group practice, and their pension situation under Section 165 (a) of the old Internal Revenue Code, was in question, although, pointing up the need for the inclusion of physicians, among others, under this section, the case will not be of significant assistance, since less than 5% of our private practitioners are involved.

Under the program proposed in the pending bills, the amount of each person's pension would be determined by his own contributions, without one cent being added by the government. In addition, the program would not force an individual into idle retirement in order to draw upon his pension fund. Most important, it presents an opportunity for all who can provide for their own retirement to do so without undue discrimination against those who work for themselves.

Mr. Chairman, these comments indicate very briefly the general viewpoint of the American Medical Association toward this legislation. Because it removes a discriminatory factor which now discourages the private practice of medicine and other professions, it is in the public interest. Because it relieves an existing inequality, it should commend itself to you. Our Association is glad to join the American Bar Association and the other great national organizations of the self-employed in urging that your Committee act favorably on these bills.

STATEMENT OF DR. FRANK G. DICKINSON ON H. R. 9 AND H. R. 10 BEFORE COMMITTEE OF THE HOUSE OF REPRESENTATIVES

My name is Frank G. Dickinson, Ph.D.—not M.D.—of Evanston, Illinois. After teaching economics at the University of Illinois for twenty-five years, I became the Director of the Bureau of Medical Economic Research of the American Medical Association for whom I am speaking today. For the past three years I have served as the American Medical Association's representative on the Coordinating Committee on Pensions for the Self-Employed and the Pensionless Employed under the chairmanship of Mr. George Roberts of the American Bar Association.

I shall, as Dr. Hamilton of our Board of Trustees has already indicated, confine my remarks to the technical aspects of these identical bipartisan bills H. R. 9 and H. R. 10. I shall refer to them as the Jenkins-Keogh bills.

I shall not dwell on the history of this proposed legislation, but during the past several years certain misconceptions have grown up about this proposed voluntary pension system. I shall try to dispel these illusions.

First, it has been implied both here and elsewhere that what we really need is lower income tax rates for every taxpayer—the self-employed as well as the employed. This is a most disturbing illusion. We are not here today to discuss the general level of income tax rates or the differences between the rates for various income groups. We are here to discuss an inequality which will not be removed by a general reduction of income tax rates. There are *only* two ways that this inequality can be eliminated: the provision for tax deferment in Section 401 can be repealed, or legislation can be enacted which abolishes the requirement of an employer-employee relationship for pension plans under Section 401. I submit that these are the only two ways of removing this obvious inequality which has been admitted widely, even by persons opposed to the Jenkins-Keogh bills.

Second, the illusion has been created that these are bills for rich men. This implies that the eleven million self-employed persons are rich and the fifty million employed persons are poor. In 1953, the average annual income of unincorporated enterprisers was $4,107 (Source: National Income, 1954 Edition, U. S. Department of Commerce). Several hundred dollars of this average income—the exact amount is not known—was derived from the ownership of land, buildings, and equipment. The average annual earnings per equivalent full-time employee, for the same year, was $3,590, or $517 less than the average income of self-employed enterprisers. For the 25 year period, 1929-1953, average incomes of self-employed enterprisers exceeded the annual average wages and salaries of those employed by others by only $316. Furthermore, in eleven of these twenty-five years the average annual incomes of self-employed enterprisers were less than the average wages and salaries of the employed. Only earned income is included in employee earnings, that is, only wages and/or salaries. Their income derived from ownership of land, other forms of wealth, and claims on wealth is excluded. This excluded income might average several hundred dollars. It seems likely that the average earned incomes of the employed and the self-employed are about equal. Needless to say, these data do not support the contention that the self-employed are richer or "better off" than the employed.

Third, it has been implied that fringe benefits for employed persons are too small to worry about, too small to complain about. In November, 1954, the Chamber of Commerce of the U. S. reported that fringe benefits for 130 identical companies amounted to 20.2% of payroll in 1953 as compared with 15.2% in 1947. Admittedly, not all of these fringe benefits are applicable to the self-employed, but pension and profit-sharing benefits are definitely applicable to the self-employed. For these two types of fringe benefits the 130 identical companies contributed 8.0% of payroll in 1953 as compared with only 5.6% in 1947. Probably two-thirds of these specific types of fringe benefits mature as retirement benefits. These are not insignificant percentages nor do they involve slight amounts of business expense to the employer. None of this business expense is currently taxable income to the employees. A further indication of the upward national trend in fringe benefits can be gleaned from even a hasty reading of newspaper accounts of the new contracts between the United Automobile Workers and the Ford Motor Company and the General Motors Corporation. This conclusion is inescapable: there is an upward trend in the United States in fringe benefits for employed persons. We live in an era of expanding fringe benefits. But the self-employed person is on the outside looking in, paying his taxes and paying a higher price for consumer goods resulting, in part, from the addition of fringe benefits to labor costs of production.

Fourth, one illusion that has been created about this bill is more disturbing than the others. I refer to the claim that the passage of the Jenkins-Keogh bills would create inequalities against employed people. I want to examine this claim very carefully. According to the U. S. Department of Commerce (National Income, 1954 Edition) $4,927,000,000 was paid out by employers in the U. S. in 1953 as contributions to private pension and welfare plans. Of this $4.9 billion, $3.1 billion was contributed by employers to all manner of profit-sharing plans that normally mature as taxable pensions to the employee. And an additional $1.4 billion was in the form of contributions by the employer to pay premiums on "free group insurance." The remaining $0.4 billion represented employer contributions to other health and welfare plans. So before this legislation could create unbalanced discriminations against employed persons, it would first be necessary to remove the existing discrimination against the self-employed—and, to some extent, against the pensionless employed. To be even more specific, the counterpart of $4.9 billion for 1954—and the figure for 1955 will surely be close to $6 billion—must be found for the self-employed taxpayers who do not participate in this large amount of currently nontaxable income received by more than 21 million persons in forms other than money income. Those who look under the bed for new discriminations that might develop from this type of legislation should examine these data from the Department of Commerce very carefully and should, moreover, appreciate the great and growing extent of present discrimination against the self-employed.

Let me try to clarify this illusion. At first thought, it would seem that the employed person covered by private pension systems would be discriminated against because this proposed legislation would provide the qualified taxpayer with a "vested" interest in the amounts he sets aside and in the interest earned on those amounts. I grant that most employer-employee pension plans do not provide for complete vesting of the employer's contribution to the pension plan and even then only after many years of service to that employer. In particular, a self-employed person under these proposed bills could move from New England to California or change from one type of employment to another without losing complete control of his personal retirement fund. But the claim that this advantage for the self-employed under these bills has no counterpart in the existing programs for the employed is in error. Furthermore, there are no provisions in these bills which provide for the full and complete vesting in the industrial pension sense of the term "vesting" until after age 65. Some of the people who are creating this illusion will grant that there is no complete vesting until age 65 but will hasten to contend that if the self-employed person died before age 65 his accumulated pension fund would become a part of his estate. We must admit the accuracy of the claim, but it is not a discrimination against the employed person whose pension is being provided by his employer. The reason is that $1.4 billion was paid out by employers in 1953 for free group insurance. If an employed person gets from his employer a free life insurance contract paying a death benefit of $5,000 for $10,000, that employee is going to leave a bigger estate than most of the self-employed taxpayers dying before the age of 65, who had responded to the deferment incentive to save for their old age under these bills. In addition, many employed persons have death benefits as a feature of their retirement plans. The self-employed is obviously one person. He has no employer. He keeps the same "employer" as long as he remains a self-employed person. Gains, even forfeitures, to the pension plan resulting from individuals' quitting and seeking employment elsewhere have no economic meaning for the self-employed.

Fifth, there is an illusion that the revenue loss to the government would exceed $100,000,000 a year from the actions of the self-employed taxpayers alone. I have presented to this Committee on two other occasions evidence that $100,000,000 is a high estimate. I have not, however, presented any estimate of the revenue loss from amounts which pensionless employed persons would set aside for their old age under this proposed legislation. For reasons which I cannot understand, the Treasury Department has not provided your Committee with estimates of revenue loss. Perhaps I, as a citizen, should not complain about the failure of the Treasury Department to offer criticism of this estimate of $100,000,000 as a maximum revenue loss from the actions of the self-employed under this proposed legislation. It should be painfully clear to everyone who gives any thought to the question that very few of the self-employed or the pensionless employed will ever put all of their eggs in one basket, in this case, all of their savings in a voluntary pension fund which these bills clearly state cannot be withdrawn until age 65 unless the qualified person dies or becomes disabled for long periods of time. The annual revenue loss on the more than $3 billion now being set aside by employers in approved plans is certainly 10 times as great.

Sixth, there is the illusion that these bills will aid only persons of high income. It is closely related to the second illusion —the notion that all the 11 million self-employed people are rich and all the 50 million employed people are poor. I have stated that there is little difference in their average incomes, but there is another point that needs to be made, namely, that the propensity to save is the major consideration. Are the rich people in your neighborhood the only ones who save money? Are the poor people in your neighborhood, employed or self-employed persons, the only ones who do not save money? This legislation would not compel anyone to save for his old age. It would encourage the self-employed and the pensionless employed to save for their old age. But the propensity to save is not confined to any one income class, to any one population group, to persons living in cities of a given size, or to one section of the country. The fact is, some people are more concerned than others about the prospect of a penniless old age. I grant that the majority of the younger self-employed—say those under 45 years of age—are not as concerned with their retirement needs. And I also grant that most of these young earners, particularly those under age 35, are in the low earning period of their lives. As they grow older they will become more proficient in their jobs, they will earn more money, and as they get closer and closer to age 65 they will think more and more about providing in advance for their old age. But the claim that this is a rich man's bill, it seems to me, is nothing but an illusion. It must be stressed over and over again that these bills would not compel anyone to save for old age. To those who believe in a free society this is one of the crowning virtues of these bills.

The seventh and last illusion refers to the amount of income that can be set aside each year into a restricted retirement fund. The general rule is 10% of earned income, but not more than $7,500 a year, subject to a lifetime limitation of $150,000 on all the amounts set aside. There is the special rule (paragraph [c], page 3) which permits more than these annual amounts to be set aside each year by those qualified taxpayers over age 55 when these bills become effective. In my previous appearances before this Committee I pointed out in great detail that these provisions would provide for the accumulation of funds which could not finance a cash refund annuity in excess of $1,000 a month starting at the age 70. I also pointed out that more than ¾ of the pension plans approved in recent years under Section 165 (a) (now Section 401 (a) of the Internal Revenue Code) would permit maximum pension in excess of $1,000 a month.

In summary, I should like to review my seven points: First, the present discrimination against the self-employed would persist under any program of general lowering of personal income tax rates. Second, on the average, the self-employed are no "richer" (income-wise) than the employed. Third, fringe benefits for employed persons are large items in the cost of production and the trend in fringe benefits is upward. Fourth, the widespread gift of free life insurance by employers to employees covered by private pension plans (and to other employees) is the counterpart of the estate created by the accumulations in the retirement fund of the self-employed who die before age 65 under the Jenkins-Keogh bills. Fifth, so far as the self-employed are concerned, the annual revenue loss to the Treasury under the Jenkins-Keogh bills will not exceed $100,000,000, as compared with the annual revenue loss on the more than $3 billion set aside annually by employers in approved pension plans. Sixth, these bills will help finance the retirement needs of only those qualified taxpayers who are willing to save, whether they are rich or poor. Seventh, by industrial pension standards only pensions of moderate amount can be financed by qualified taxpayers under these bills.

I submit that these are reasonable demands for equality but I have also in my previous testimony expressed regret that I was not appearing before you in support of a simple resolution—a resolution that would direct the Treasury Department to draft rules whereby the self-employed could establish individual retirement plans, giving them the same tax encouragement to save for old age as is now provided more than 21 million officers and employees of corporations and employees of other establishments and organizations. No doubt the number of approved pension plans is now approaching 30,000 and the number of existing plans, 25,000. If my guess is about right—and the Treasury Department can correct me—there are now not more than 30,000,000 pensionless employed persons.

As a member of the Coordinating Committee, and as an individual, I have given a great deal of thought to an amendment to H. R. 9 and H. R. 10 which would accomplish what I sought by a simple resolution.

At the outset I should like to make it very plain that this amendment has not been considered by the American Medical Association, and is submitted to the Committee for the purpose of study. If it should be incorporated in a bill, or otherwise be presented in printed form as a proposal before this Committee, it will be reviewed in that form by the appropriate bodies of the American Medical Association.

Congressman Keogh, the lawyers representing the American Bar Association, and certain persons on the staff of the Legislative Counsel have helped in drafting this amendment. Moreover, I have been assured by other lawyers that my proposal—which I call the "9th decile limits"—is not an unconstitutional transfer from the Congress to the Treasury Department of the power to enact tax laws.

With the understanding that this amendment has not been considered by the American Medical Association, I should like to present as a final part of my testimony on the illusions that have grown up about the Jenkins-Keogh bills, the basic ideas and the technical features of this proposed amendment, unless the Committee already has received sufficient information from those witnesses who have preceded me.

NATIONAL COMPULSORY DISABILITY BENEFITS

The following news release was issued from the American Medical Association, July 15, 1955.—Ed.

Dr. Gunnar Gundersen, La Crosse, Wis., Chairman of the Board of Trustees of the American Medical Association, said today that a Democratic-sponsored plan to extend social security payments to the disabled and to raise taxes to pay for them is "strictly a political maneuver to influence votes."

"If the American people are going to retain their right to spend their money as they wish, they must stand up now and vigorously fight these super-Santa Claus proposals born of politics," Dr. Gundersen said, adding: "The proposals contained in this bill, which was sent to the House last Tuesday, actually provide an illusory benefit at the cost of ever-increasing taxation and loss of personal freedom." Speaking out after the House Ways and Means Committee approved the Social Security proposals by a vote of 21 to 3, Dr. Gundersen said: "A move by the majority of the Committee to railroad through the House an amendment to the Social Security Act which would provide national compulsory disability insurance without public hearings is an outrage. It is not easy to criticize national legislation which superficially appears to be a humanitarian effort to help disabled persons, and it takes courage for a politician to oppose it. Therefore, it is imperative that the American people take a strong stand against this proposal which, if adopted, will go far toward the nationalization of medicine.

"The levying of additional Social Security taxes by the federal government in order to distribute cash benefits to the permanently and totally disabled would inevitably be followed by federal control of the nation's physicians, who would be forced to carry out the regulations established by the government. It is incredible that Congress would consider legislation of such far-reaching implications without a full opportunity for public hearings. The fact is that only four states—New York, New Jersey, Rhode Island and California—have adopted similar legislation and most of the other states have considered and rejected it. In one state—Washington—where the people were given an opportunity through public referendum to pass on it, a bill to establish compulsory state sickness insurance was defeated three to one.

"This federal proposal includes an immediate 25 per cent boost in Social Security taxes and unpredictable future tax increases. A program already exists whereby the federal government and the states jointly participate in providing financial assistance to the permanently and totally disabled who are in need of it. In addition, over 40 million persons are covered by private insurance companies against loss of income because of disability. This legislation is another example of unnecessary federal invasion of a rapidly developing area of private enterprise."

MEDICAL NEWS

CALIFORNIA

Grant for Chronic Disease Studies.—To assist in the epidemiological studies of the bureau of chronic diseases of the California Department of Public Health, the Rockefeller Foundation recently appropriated $150,000 for a five year period. Among the problems being studied by the California bureau are the relation of occupation and heart disease; occupation and cigarette smoking as factors in lung cancer; nutrition in the health of older persons; and methods of morbidity measurement in the general population. The bureau during the past five years has extended its work, establishing working relationships with universities, local health departments, medical societies, and similar agencies useful in gaining access to and observing specific population groups.

Society News.—The California Society of Plastic Surgeons recently elected the following officers: Dr. James B. Johnson, Beverly Hills, president; Dr. Gerald B. O'Connor, San Francisco, vice-president; and Dr. Benjamin F. Edwards, Los Angeles, secretary-treasurer. The sixth annual meeting will be held at the Del Monte Lodge, Del Monte, March 22-24, 1956.——The following officers were elected by the California Society of Allergy at its annual meeting in San Francisco May 2: president, Dr. Lazarre J. Courtright, San Francisco; president-elect, Dr. Ben C. Eisenberg, Huntington Park; and secretary-treasurer, Dr. William J. Kerr, San Rafael.——The recently established California chapter of the American Foundation for Allergic Diseases has elected the following physician members of the board of directors: Ralph Bookman and George Piness, Los Angeles; Ben C. Eisenberg, Huntington Park; D. Edward Frank, Sun Valley; and Walter R. MacLaren, Pasadena.

MASSACHUSETTS

Appointments in Ophthalmology.—Drs. David G. Cogan and Walter M. Grant have been appointed professor and associate professor of ophthalmology, respectively, at the Harvard Medical School, Boston. They will continue their research and teaching at the Howe Laboratory, Massachusetts Eye and Ear Infirmary, which has been maintained by the Harvard Medical School since 1927.

Poison Information Center.—The Boston Poison Information Center, a cooperative venture of the four pediatric teaching services in the city, has been established at the Children's Medical Center, 300 Longwood Ave., under the sponsorship of the committee on accident prevention of the Massachusetts chapter of the American Academy of Pediatrics. Calls will be received at BEacon 2-2120 at any hour. Information may be obtained from the executive secretary, Dr. Lendon Snedeker (BEacon 2-7800). This service is available to any physician.

Personal.—The University of Louisville conferred an honorary doctor of science degree on Dr. Frederick H. Verhoeff, consulting chief of the Massachusetts Eye and Ear Infirmary, Harvard Medical School, Boston, at commencement exercises June 5. On June 6 Dr. Verhoeff spoke at the annual postgraduate seminar of the University of Louisville (Ky.) School of Medicine.——Dr. A. Clifford Barger, associate in physiology at Peter Bent Brigham Hospital, Boston, has been appointed associate professor of physiology at the Harvard Medical School.——Dr. Alfred H. Stanton, chief of the psychiatric closed ward section of the Veterans Administration Hospital, Boston, and assistant professor of psychiatry, Boston University School of Medicine, has been appointed psychiatrist-in-chief of the McLean Hospital, Waverley, and associate professor of psychiatry, Harvard Medical School, Boston.——John F. Enders, Ph.D., Brookline, a 1954 Nobel laureate in medicine, was awarded the honorary degree of doctor of science at the 129th commencement of Trinity College, Hartford, Conn. Dr. Enders is associate professor of bacteriology and immunology at Harvard Medical School, chief of the research department of infectious diseases at Children's Medical Center, Boston, and president of the American Association of Immunologists.

MICHIGAN

Diabetic Children's Camp.—There are a few openings left for Camp Midicha, the camp for diabetic children sponsored by the Michigan Diabetes Association and the Tau Beta Society. The fee for this camp will be based on the ability of the family to pay. The season is Aug. 14 to Aug. 24. For reservations call Dr. Kathryn L. O'Connor, BR 3-0350, before July 25.

NEW JERSEY

Contest in Orthopedic Surgery.—The New Jersey Orthopaedic Society will make an award annually of $100 in cash for the best original paper in English in the field of orthopedic surgery submitted by an intern or resident (in any field) in a New Jersey hospital. The paper may cover any aspect of the field, such as pathogenesis, pathology, diagnosis, and treatment. The work on which the paper is based must have been done during, and completed not later than six months after, internship or residency in a New Jersey hospital. The paper should be submitted for the current award to the secretary of the society, Dr. Arthur S. Thurm, 533 W. State St., Trenton 8. The winner of the award will be invited to present the paper personally at the spring meeting of the society.

NEW YORK

Dr. Sawyer Receives Kaiser Award.—At the annual meeting of the Rochester Academy of Medicine May 24, the Albert David Kaiser medal for 1955 was awarded to Dr. William Alfred Sawyer, Rochester, "for his distinguished contribution and dedicated service to industrial medicine and to the health and welfare of our community and nation." Dr. Sawyer retired four years ago as medical director of the Eastman Kodak Company after 32 years of service. He is a former president of the Industrial Medical Association and holds the Knudsen award, which he received in 1943.

Dr. Potter Appointed Dean.—Dr. Howard W. Potter, acting dean of the State University of New York College of Medicine at New York City, Brooklyn, has been appointed dean of the college. Dr. Potter, who has been a faculty member for 15 years, has been professor and chairman of the department of psychiatry. Previously, he was a member of the New York Psychiatric Institute of the state department of mental hygiene and clinical professor of psychiatry at Columbia University College of Physicians and Surgeons. During World War II, he was medical supervisor of the Port of New York for Merchant Marine War Shipping Administration, engaged in the rehabilitation of seamen from torpedoed ships. Dr. Potter is a past-president of the American Association on Mental Deficiency, the New York Society for Clinical Psychiatry, and the New York Psychiatric Society.

Society News.—The New York Diabetes Association announces the removal of its offices from 2 E. 103rd St. to Rooms 405 and 406, Building A, 270 Park Ave., New York 17 (telephone: PLaza 3-2266).——Newly elected officers of the New York Academy of Gastroenterology include: Dr. Franz J. Lust, New York City, president; Drs. A. Xerxes Rossien, Kew Gardens, Jerome A. Marks, New York City, and Milton J. Matzner, Brooklyn, first, second, and third vice-presidents respectively; Dr. Joseph Roger Van Dyne, Forest Hills, secretary; Dr. Alexander Slanger, Brooklyn, recording secretary; and Dr. William C. Jacobson, New York City, treasurer.——Newly elected officers

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

of the Nassau branch of the American Psychiatric Association include: Dr. Lester Shapiro, Rockville Centre, president; Dr. Ursula G. Stewart, Elmont, vice-president; and Dr. Irving Chipkin, Hempstead, secretary.——The Medical Society of the County of New York recently elected the following physicians from New York City as officers: Dr. Gerald D. Dorman, president; Dr. Samuel Z. Freedman, president-elect; Dr. Philip D. Allen, vice-president; Dr. William L. Wheeler Jr., secretary; Dr. George Himler, assistant secretary; Dr. George W. Fish, treasurer; and Dr. Charles F. Stewart, assistant treasurer.

Two-Way Radio for Postgraduate Education.—A new technique of classroom instruction will be launched this fall by Albany Medical College as part of its postgraduate medical education program, under a grant from the Rockefeller Foundation. It envisions the use of a "master transmitter" at the college, which will send lectures and discussions of the teaching staff via high-frequency "amateur" wave lengths to special receivers located in hospitals in the eastern part of upstate New York, where transmitters operating on the same wave length will permit physicians hearing the instructions to take active part in the sessions. The physicians may interpose questions and have them answered immediately by the instructors. There will be opportunity for free discussion between instructors and postgraduate students. It is expected that about 10 institutions will take part. Test sessions indicate that the effective range of the broadcasts may be about 75 miles. The broadcasts will be made on prearranged schedules, and physicians will assemble at the hospitals nearest them to listen to the teaching sessions. The college will continue to conduct its regular program of postgraduate medical education as well as its special teaching days. Dr. Frank M. Woolsey Jr., associate dean, is director of postgraduate education.

New York City

Hospital News.—The Roosevelt Hospital has appointed a full-time clinical research editor, who will assist the staff with bibliography searching, abstracting, and editing of articles and reports for publication.——The Bronx Hospital recently dedicated its new $800,000 Louis Altschul Laboratory building, a two story center adjacent to the main building at Fulton Avenue and 169th Street. The building houses the Bronx Hospital's departments of pathology, chemistry, bacteriology, and related laboratories, in addition to research laboratories for its departments of medicine and surgery. The second floor provides living quarters for the house staff of interns and residents as well as an auditorium.

Cystic Fibrosis Association.—The first of a series of grants for research in cystic fibrosis was recently made by the Cystic Fibrosis Association to the Presbyterian Hospital at the Columbia-Presbyterian Medical Center. The association was organized by a group of 35 parents of children with cystic fibrosis, who early this year began a fund-raising campaign and who on April 1 officially organized the Cystic Fibrosis Association. Their membership has more than tripled and now includes parents from New York, Connecticut, and New Jersey. The association's headquarters, opened early in June, are in the Hotel Martinique, Broadway and 32nd Street. Research work under the grant will be directed by Dr. Dorothy H. Andersen, associate attending pathologist and associate professor of pathology, and Dr. Paul di Sant'Agnese, assistant professor of pediatrics, Columbia University College of Physicians and Surgeons.

Courses in Physical Rehabilitation.—The Institute of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center, 400 E. 34th St., will offer a three week seminar in physical rehabilitation methods for nurses, Oct. 24-Nov. 11; Jan. 9-27, 1956; and April 2-20. The course is designed for registered nurses in the hospital as well as in the public health fields. Tuition is $60 for the seminar and $20 weekly for additional clinical observation, practice, and field trips. The institute will also offer a four week advanced course in physical rehabilitation methods for physical therapists, Nov. 21-Dec. 16; Feb. 6-March 2, 1956; and April 30-May 25. Four points of either undergraduate or postgraduate credit will be given. Tuition, $80 ($20 per point); registration, $8. Qualified veterans may enroll in the course under the provision of P. L. 346 or P. L. 16. Information may be requested from Mrs. Edith Buchwald Lawton, Director of Rehabilitation Courses for Physical Therapists, Institute of Physical Medicine and Rehabilitation, 400 E. 34th St., New York 16.

NORTH CAROLINA

Society News.—The North Carolina Pediatric Society recently elected Dr. Wilburt C. Davison, Durham, president; Dr. Charles F. Williams, Raleigh, president-elect; and Dr. William Hersey Davis Jr., Winston-Salem, secretary-treasurer.

Personal.—The North Carolina Public Health Association recently bestowed its Carl V. Reynolds award on Dr. Margery J. Lord, health officer of Asheville for 15 years, and on Dr. Frederick J. Wampler, health officer, Granville County.

Conference on Tuberculosis Control.—The theme for the sixth Institute on Problems in Tuberculosis Control, Chapel Hill, July 31-Aug. 3, will be "Tackling Community Roadblocks Encountered in Rehabilitating the Patient." The institute will be sponsored by the North Carolina Tuberculosis Association; the schools of public health, social work, and medicine of the University of North Carolina, Chapel Hill; the division of vocational rehabilitation; the sanatoriums; and the state boards of health and of public welfare.

Dr. Lawrason Goes to Arkansas.—Dr. F. Douglas Lawrason, assistant dean, University of North Carolina School of Medicine, Chapel Hill, has been appointed provost for medical affairs and acting dean of the University of Arkansas School of Medicine, Little Rock. Dr. Lawrason, who will assume his new duties Aug. 1, will be the chief administrative officer of the new health center, consisting of a 500-bed hospital, with schools of medicine, nursing, and pharmacy. Dr. Lawrason has served as assistant professor of medicine at Chapel Hill since August, 1953. Previously he was on the staff of the Yale University School of Medicine, New Haven, Conn., and with the National Research Council of the National Academy of Sciences in Washington, D. C.

PENNSYLVANIA

Society News.—The Pennsylvania Academy of Physical Medicine and Rehabilitation recently elected the following officers: Dr. Joseph F. Dreier, Wilkes-Barre, president; Dr. James S. Martin, Lancaster, vice-president; and Dr. J. Murl Johnston, Pittsburgh, secretary-treasurer.

Colonel Whayne Appointed Professor.—Col. Tom F. Whayne, U. S. Army Medical Corps, retired, has been appointed professor of public health and preventive medicine at the University of Pennsylvania School of Medicine, Philadelphia, and coordinator of the program of medical education for national defense in the school of medicine.

Philadelphia

University News.—Dr. Elizabeth V. Lautsch, McGill University Faculty of Medicine, Montreal, Canada, has joined the faculty of the Woman's Medical College of Pennsylvania as associate in pathology.

Kober Medal to Dr. Stadie.—At the annual meeting of the Association of American Physicians in Atlantic City, Dr. William Christopher Stadie received the Kober medal, awarded annually by the Kober Foundation at Georgetown University, Washington, D. C., to a member of the association. Dr. Stadie, who was assistant professor of medicine at Yale University School of Medicine, New Haven, Conn., from 1921 to 1924 and assistant professor of research medicine at the University of Pennsylvania from 1924 to 1941, has since served the latter as John Herr Musser Professor of Research Medicine. The Kober Medal is provided for by a $16,000 endowment fund, established in 1923 by the late Dr. George M. Kober to commemorate the 50th anniversary of his graduation in medicine from Georgetown. The fund also pays the expenses of an annual lecture on a medical subject, a scholarship in the Georgetown University School of Medicine, and a gold medal awarded to the best student in hygiene.

WASHINGTON

Bacteriologists Needed.—The Washington State Personnel Board announces an examination for bacteriologists. There is one current opening with the laboratory of the state department of health in Seattle. Positions are also found in local health department laboratories throughout the state. Vacancies occurring in the next two years may be filled by appointments from the eligible list to be established at this time. Applicants must be graduates of an accredited four year college or university, with a major in medical microbiology or a comparable major (medical or public health bacteriology) including laboratory course work in pathogenic bacteria, serologic diagnosis, water and milk bacteriology, and chemistry. Applicants with courses in parasitology, immunology, qualitative and quantitative chemical analysis, physics, mathematics, and zoology will be given preference in appointments. Residence in the state of Washington is not required, but state residents may be given preference in appointment. Applicants must be United States citizens. Applications will be accepted until 5 p. m. Aug. 1, 1955. Information is available from State Personnel Board, 1069 Capitol Way, Olympia (mailing address, P. O. Box 688, Olympia).

WISCONSIN

Hospital News.—Dr. Ernst Schmidhofer, formerly affiliated with the Veterans Administration Center in Jackson, Miss., has been appointed medical director of the Milwaukee County Asylum for Chronic Insane, a position left vacant since the death of Dr. Ralph M. Fellows. Dr. Morris Gelfman, who was formerly with the Veterans Administration Hospital at Downey, Ill., has been named clinical director of the asylum.

Society News.—Drs. Robert G. Washburn, Milwaukee, and Maynard H. Fuller, Green Bay, have been awarded life memberships in the State Medical Society of Wisconsin in recognition of their "achievements in the ranks of medicine." Dr. Washburn served as staff dermatologist for Columbia, St. Mary's, and Milwaukee Children's hospitals. Dr. Fuller has served as president and secretary of the Brown-Kewaunee-Door County Medical Society.

Rare Medical Circulars Sought.—Two rare medical circulars concerning the University of Wisconsin Medical School, Madison, and a private hospital, the Lake Side Retreat, once located on the south margin of Lake Menona near the site of the new headquarters of the State Medical Society of Wisconsin are being sought by the state historical society and the section on medical history of the state medical society. Clues to the circulars, no copies of which are known to exist, are given in a letter, dated Feb. 8, 1857, from Dr. Alexander Schue, former Madison physician and surgeon, to Dr. Robert Peter, chemist of Transylvania College. Any physician knowing of these circulars is urged to contact Dr. William D. Stovall, Chairman, Section on Medical History, State Medical Society of Wisconsin, Box 1109, Madison 1.

GENERAL

Urology Award.—The American Urological Association offers annual awards equaling $1,000 (first prize of $500, second prize $300, and third prize $200) for essays on the result of some clinical or laboratory research in urology. Competition is limited to urologists who have been graduated not more than 10 years and to men in training to become urologists. The first prize essay will appear on the program of the forthcoming meeting of the American Urological Association, to be held at the Statler Hotel, Boston, May 28-31, 1956. For particulars write the Executive Secretary, William P. Didusch, 1120 North Charles St., Baltimore. Essays must reach him before Dec. 1, 1955.

Kappa Delta Award.—A prize of $1,000, donated by the Kappa Delta Sorority, is offered annually by the American Academy of Orthopaedic Surgeons for the best research related to orthopedic surgery and performed by an American citizen in the United States. Selection for the current year will be made from publications after Jan. 1, 1953, or research presented to the committee on scientific investigation of the American Academy of Orthopaedic Surgeons before Nov. 1, 1955. Researchers may secure information from the Chairman of the Committee on Scientific Investigation of the American Academy of Orthopaedic Surgeons, Dr. Paul R. Lipscomb, 200 First St., S. W., Rochester, Minn.

Symposium in Psychiatry.—A two day symposium will be held as part of the program of the American Association for the Advancement of Science Dec. 27-28 at Atlanta, Ga. The symposium, "Physiological Bases in Psychiatry," will have four sessions: "New Psychopharmacological Agents," "Mechanisms of Actions in New Agents," "Effects of Alcohol on Brain Respiration and Metabolism," and "Alcohol Addiction-Mechanisms and Treatment." Those wishing to take part in this program may contact either Dr. Harold E. Himwich, Galesburg State Research Hospital, Galesburg, Ill., who is a representative of the American Psychiatric Association, or Fred A. Hitchcock, Ph.D., Ohio State University, Columbus 10, Ohio, who is a representative of the American Physiological Society.

Glycerine Research Awards.—The Glycerine Producers' Association is accepting nominations for the fourth annual Glycerine Research awards. First award is $1,000 and an honor plaque; second award, $300 and an honor certificate; and third award, $200 and an honor certificate. Research bearing on the chemical, physical, or physiological properties of glycerine or on the properties of glycerine-derived or glycerine-containing materials is eligible. Work exhibiting originality in extending glycerine's usefulness in new applications will merit special consideration. Nominations, made on official entry blanks, must be received by Nov. 1, 1955. Details can be obtained by writing to the Awards Committee, Glycerine Producers' Association, 295 Madison Ave., New York 17.

Awards to Teach in Foreign Countries.—Announcement is made of U. S. government awards for the academic year 1956-1957, authorized under the Fulbright Act and presented under the auspices of the Department of State and the Board of Foreign Scholarships. Awards are available for university lecturing and advanced research in Austria; Belgium and Luxembourg; Denmark; Finland; France; Germany; Greece; Iraq; Italy; Japan; Netherlands; Norway; Pakistan and East Pakistan; and the United Kingdom colonial dependencies. Applicants must be United States citizens. Information is obtainable from the Conference Board of Associated Research Councils, Committee on International Exchange of Persons, 2101 Constitution Ave., Washington 25, D. C.

Children's Exocrine Research Foundation.—The Children's Exocrine Research Foundation, a nonprofit organization, has recently been formed to encourage and support research in cystic fibrosis of the pancreas and to disseminate knowledge concerning this disease to the medical profession. Research will also include work on closely related conditions. The foundation, with headquarters at 2300 Westmoreland St., Philadelphia, will welcome applications for research grants. Dr. Sidney Farber, Boston, is chairman of the Scientific Advisory Board and Dr. Paul R. Patterson, Albany, N. Y., is chairman of the Medical Education Committee. The organization does not conduct public campaigns or solicit funds from the general public. Money is raised through grants from other foundations interested in medical research and from selected corporations and individuals.

Fellowship in Rheumatic Fever.—The New York State Department of Health has made available a grant to provide a fellowship in rheumatic fever of one year for a physician with a good general or pediatric background who lacks specific training in this field. Priority will be given to a physician wishing to make full-time teaching, research, or public health a career and who has an interest in children's rheumatic fever and related programs. The major part of the training will be at the New York University-Bellevue Medical Center and at Irvington House, a special institution at Irvington-on-Hudson, N. Y., for rheumatic children, affiliated with the New York University-Bellevue Medical Center. The budget for the fellowship is as follows: (1) stipend, $4,200; (2) travel expenses, $800. Applicants should write to the Medical Director, Irvington House, Irvington-on-Hudson, N. Y.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States and its territories and possessions in the weeks ended as indicated:

FOREIGN

Symposium Neuroradiologicum.—A Symposium Neuroradiologicum will be held in London, England, Sept. 13 to 17 at the University of London, Malet Street, W. C. 1. Radiologists, neurologists, and neurosurgeons particularly are welcome. The subjects for discussion include (1) cerebrovascular disease, (2) localization of intracranial tumors by means of isotopes, (3) applications of stereotaxometry, (4) new techniques, and (5) various preferred papers on a variety of neuroradiological subjects. Participants from the United States include: Dr. Harry A. Kaplan, Brooklyn, N. Y.; Drs. Juan M. Taveras and Fritz J. Cramer, New York City; Drs. William H. Sweet and Bertram Selverstone, Boston; and Drs. Frederick Murtagh and Ernest A. Spiegel, Philadelphia. A joint half-day session with the second International Congress of Neuropathology, meeting simultaneously in London, is projected. A social program has been arranged. Information may be obtained from Dr. R. D. Hoare, Secretary, Symposium Neuroradiologicum, The National Hospital for Nervous Diseases, Queen Square, London W. C. 1.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

1956 Clinical Meeting, Seattle, Nov. 27-30.

1957 Annual Meeting, New York, June 3-7.

American Medical Association Public Relations Institute, Drake *Hotel, Chicago, Aug. 31- Sept. 1.* Mr. Leo E. Brown, 535 N. Dearborn St., Chicago 10, Director.

American Association of Nursing Homes, Hotel Muehlebach, Kansas City, Mo., Sept. 19-21. Mr. Ira O. Wallace, P.O. Box 366, New Castle, Ky., Secretary.

American Association of Obstetricians, Gynecologists and Abdominal *Surgeons, The Homestead, Hot Springs,* Va., Sept. 8-10. Dr. Frank R. Lock, Bowman Gray School of Medicine, Winston-Salem, N. C., Secretary.

American Congress of Physicial Medicine and Rehabilitation, Hotel Statler, Detroit, Aug. 28-Sept. 2. Dr. Frances Baker, 30 North Michigan Ave., Chicago 2, Secretary.

American Physiological Society Fall Meeting, Tufts College, Medford, *Mass., Sept. 6-9.* Dr. Allan C. Burton, Univ. of Western Ontario, London, Ont., Canada, Secretary.

American Veterinary Medical Association, Radisson Hotel and Auditorium, Minneapolis, Aug. 15-18. Dr. J. G. Hardenbergh, 600 South Michigan Blvd., Chicago 5, Executive Secretary.

Biological Photographic Association, Wisconsin Hotel, Milwaukee, Aug. 30-Sept. 2. Miss Jane H. Waters, c/o Pavelle Color, Inc., 533 W. 57th St., New York 19, Executive Secretary.

Montana Medical Association, Baxter Hotel, Bozeman, Sept. 15-18. Mr. L. R. Hegland, P.O. Box 1692, Billings, Executive Secretary.

National Medical Association, Los Angeles, Aug. 8-11. Dr. John T. Givens, 1108 Church St., Norfolk 10, Va., General Secretary.

Nevada State Medical Association, Riverside Hotel, Reno, *Aug. 18-20.* Dr. William A. O'Brien III, 505 Chestnut St., Reno, Secretary.

New England Health Institute, Colby College, Waterville, Me., Aug. 30-Sept. 1. Dr. Edward W. Colby, City of Portland Health Dept., Portland, Me., Chairman.

Pacific Dermatologic Association, Mexico, D. F., Mexico, Aug. 22-24. Dr. Ben A. Newman, 436 N. Roxbury Drive, Beverly Hills, Calif., Secretary.

Regional Meetings, American College of Physicians:

Jamestown, N. D., Sept. 10. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Executive Secretary.

Reno Surgical Society, Reno, Nev., Aug. 18-20. Dr. James R. Herz, 509 Humboldt St., Reno, Nev., Secretary.

Rocky Mountain Radiological Society, Shirley-Savoy Hotel, Denver, Aug. 18-20. Dr. John H. Freed, 4200 East 9th St., Denver 20, Secretary.

Society of General Physiologists, Marine Biological Laboratory, Woods Hole, Mass., Sept. 9-10. Dr. A. M. Shanes, National Institutes of Health, Bethesda 14, Md.

Southwestern Surgical Congress, Muehlebach Hotel, Kansas City, Mo., Sept. 5-7. Dr. C. M. O'Leary, 207 Plaza Court Bldg., Oklahoma City, Secretary.

U. S. Chapter, International College of Surgeons, Convention Hall, Philadelphia, Sept. 12-15. Dr. Karl Meyer, 1516 Lake Shore Drive, Chicago 10, Secretary.

Utah State Medical Association, Union Bldg., Salt Lake City, Sept. 8-10. Mr. H. Bowman, 42 S. Fifth East St., Salt Lake City 2, Executive Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 11-14. Dr. Frederick A. Tucker, 1309 Seventh Ave., Seattle 1, Secretary.

West Virginia State Medical Association, White Sulphur Springs, Aug. 18-20. Mr. Charles Lively, P. O. Box 1031, Charleston 24, Executive Secretary.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Part I, Sept. 6-7. Candidates may file applications at any time, but the National Board must receive them at least six weeks before the date of the examination. New candidates should apply by formal registration; registered candidates should notify the board by letter and forward their fees. Exec. Sec., Dr. John B. Hubbard, 133 South 36th St., Philadelphia 4.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* New York City, Oct. 23-27. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15.

American Board of Dermatology and Syphilology: *Oral.* Washington, D. C., Oct. 14-16. Final date for filing application was March 15. Sec., Dr. B. M. Kesten, One Haven Ave., New York 32, N. Y.

American Board of Internal Medicine: *Oral.* Portland, Ore., Sept. 14-16; Chicago, Nov. 30-Dec. 1. *Subspecialties. Cardiovascular Disease.* Chicago, Nov. 30. The closing date for acceptance of applications for gastroenterology was Feb. 1, and for cardiovascular disease the closing date was June 1. Exec. Sec., Dr. William A. Werrell, 1 West Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* New Haven, November. Oral examinations given in Spring and Fall. Final date for filing application for the Spring examination is October 1; for the Fall examination April 1. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: Applications for certification for the 1956 Part I examinations are now being accepted. Final date for filing application is Oct. 1. Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Practical Examination.* Chicago, Oct. 9-14. Final date for filing application for 1955 practical examination was July 1, 1954. *Written.* January, 1956. Final date for filing application was July 1. *Practical Examination.* St. Louis, Oct. 20-25. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery: Final date for filing application for the Part II examination to be given in January 1956 is Aug 15. Sec., Dr. Harold A. Sofield, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 3-7. Final date for filing application is April. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pediatrics: *Oral.* Chicago, Oct. 7-9; and Washington, D. C., Dec. 2-4. Admin. Sec., Mrs. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: *Oral and Written.* Philadelphia, Sept. 22-24. Corres. Sec., Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Preventive Medicine: *Certification in Public Health.* Kansas City, Mo., Nov. 10-12. Sec.-Treas., Dr. Ernest L. Stebbins, 615 N. Wolfe St., Baltimore 5.

American Board of Proctology: *Part II.* Philadelphia, Sept. 17. Sec., Dr. Stuart T. Ross, 131 Fulton Ave., Hempstead, N. Y.

American Board of Psychiatry and Neurology: San Francisco, mid-October; New York City, December. Sec., Dr. David A. Boyd, 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Radiology: Chicago, Dec. 4. Final date for filing applications for the fall examination was July 1. Candidates who will complete their training by Dec. 31 will be eligible to appear for this examination. Sec., Dr. B. R. Kirklin, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Part I.* Centers throughout the United States, in Europe and in the Far East, Oct. 26 and March 28. Closing date for the October examination was July 1 and for the March examination is December 1. *Part II.* Buffalo, Sept. 26-27; Chicago, Oct. 27-28; New York City, Nov. 14-15; St. Louis, Dec. 12-13; New Orleans, Jan. 16-17; Los Angeles, Feb. 13-14; San Francisco, Feb. 16-17; Durham, Mar. 12-13; Boston, May 14-15 and Philadelphia, June 4-5. Sec., Dr. John B. Flick, 255 S. Fifteenth St., Philadelphia 2.

The Board of Thoracic Surgery: *Written.* Various Centers, Sept. 9. Final date for filing applications was July 1. Sec., Dr. Wm. M. Tuttle, 1151 Taylor Ave., Detroit 2.

MAGAZINE–TELEVISION REPORT

The following list of current medical articles appearing in mass-circulation magazines on medical subjects is published each week only for the information of readers of The Journal. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles herein reported.*

MAGAZINES

Life, July 11, 1955

"Mental Illness: The New Hope"

In a full-page editorial, *Life* editors say that "signs of a double breakthrough (psychiatric treatment and new drugs) on our No. 1 disease justify a national effort." The editorial says the solution to the problem is not in building more hospitals. "It is in emptying the ones we have—by preventing new cases from developing and by getting the existing ones out." *Life* concludes: "the goals should be threefold—to train thousands of new psychiatrists to remedy the present inadequacy, to finance scores of low-cost psychiatric clinics where mental illness can be checked before it grows serious, and finally to finance much greater research into the whole field of mental chemistry."

U. S. News & World Report, July 15, 1955

"What You Should Know About Health," interview with Dr. Robert Collier Page

A past-president of the Industrial Medical Association answers questions on health problems of executives and employees. He points out that an industrial physician works closely with the family physician. He treats only in an emergency and refers executives and employees to private physicians when medical care is indicated.

American Legion Magazine, July, 1955

"Public Health Disgrace No. 1," by Caroline Bird

U. S. Public Health Service Veterinarian Dr. James H. Steele calls rabies "our number one public health disgrace." He urges action to eliminate the problem. According to the article, "the only way to wipe out rabies in the United States is to get 70 per cent of our dog population vaccinated and keep that percentage vaccinated by enforcing dog control laws."

Coronet, August, 1955

"X-Rays Can Be Dangerous," by Lydia Strong

Wilhelm Konrad von Röntgen's discovery of the x-ray in 1895 "revolutionized medicine." In spite of its great value, "The National Committee on Radiation Protection . . . points out forcefully the need for doctors 'to exercise great caution and restraint in the use of x-rays for diagnosis and the treatment of nonmalignant diseases.' " The article warns patients against demanding x-ray treatment and urges them to let the doctor decide whether radiation is necessary.

"The Newest Facts About Baldness," by Veronica L. Conley

Condensed from *Today's Health,* this article by the Assistant Secretary of the American Medical Association's Committee on Cosmetics points out that cures for baldness have one thing in common—"they fail to grow hair." She says "the physician's greatest task is usually assisting the young man to make an adequate adjustment to this cosmetic disturbance, with which he will have to live for the rest of his life."

"Ceiling of Hope," by Gerald Nelson

A nonprofit organization manufactures ceiling projectors and films for use in sickrooms and hospitals. In connection with this article, American Medical Association President Dr. Elmer Hess says: "The morale and mental well-being of a bedridden patient is of extreme importance. Any device that can while away the hours for a sick person—like the ceiling projector reported in this *Coronet* article—is indeed a blessing."

Saturday Evening Post, July 16, 1955

"Healing by High Frequency," by Milton Silverman

"Last year . . . it was estimated that more than 4,000 ultrasonic devices were being used in this country alone to treat several hundred thousand patients afflicted with a wide assortment of painful, crippling ailments of bones, joints and muscles. The sound beams . . . were rarely if ever curative in themselves, but combined with other forms of treatment and administered by skilled and experienced physicians, they were giving significant relief to many of the victims."

"How to Avoid Sudden Death," by Steven M. Spencer

In an article recommending the use of automobile seat belts, the author reports on the medical profession's active interest in this campaign. He quotes Dr. R. Arnold Griswold, chairman of the American College of Surgeons' Committee on Trauma, and Dr. Horace E. Campbell, chairman of the Automobile Safety Committee of the Colorado State Medical Society.

DEATHS

Adams, James Frederick, Catonsville, Md.; University of Maryland School of Medicine, Baltimore, 1894; died in the University Hospital, Baltimore, June 10, aged 85, of carcinoma of the prostate.

Andrus, Adellon Devilla ⊕ Ashland, Wis.; University of Colorado School of Medicine, Denver, 1912; served during World War I; at one time a medical officer of the Indian Service; died May 22, aged 72, of heart disease.

Armentrout, Charles Henry ⊕ Asheville, N. C.; Medical College of Virginia, Richmond, 1931; specialist certified by the American Board of Surgery; commissioned in the U. S. Naval Reserve during World War II and was awarded the Unit Citation and the Purple Heart; fellow of the American College of Physicians; on the staffs of the Memorial Mission and St. Joseph's hospitals; senior consultant in medicine at Veterans Administration Hospital in Swannanoa, N. C.; died in the Memorial Mission Hospital May 19, aged 47, of coronary thrombosis.

Bookmyer, Ralph Hugh ⊕ Detroit; Detroit College of Medicine and Surgery, 1915; fellow of the American College of Surgeons; served on the staffs of the Providence and Mount Carmel Mercy hospitals; died June 7, aged 71, of acute coronary thrombosis.

Braff, Max Mark, Boston; Boston University School of Medicine, 1917; served during World Wars I and II; member of the Massachusetts Medical Society; died in the Beth Israel Hospital June 7, aged 63, of cerebral hemorrhage.

Collins, George Robert, Avon, N. Y.; University of Buffalo School of Medicine, 1912; health officer for the town and village of Avon; served as a member of the board of education of Avon Central School and for many years its school physician; died April 27, aged 66, of coronary occlusion.

Cooper, John Steward Stevens, Lansdowne, Pa.; Jefferson Medical College of Philadelphia, 1891; died Feb. 18, aged 86, of carcinoma of the colon.

Doerann, August Frederick ⊕ Evanston, Ill.; Illinois Medical College, Chicago, 1906; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; died in St. Francis Hospital June 12, aged 75, of gastrointestinal hemorrhage and gastric ulcer.

Epstein, Jacob Israel ⊕ Cleveland; Tufts College Medical School, Boston, 1927; on the staff of the Crile Hospital; died in Ravenna May 6, aged 51, in an automobile accident.

Fayerweather, Rhoades, Kahuku, Hawaii; Johns Hopkins University School of Medicine, Baltimore, 1903; died Feb. 1, aged 77, of coronary occlusion.

Franks, Arthur Jr. ⊕ Harrisburg, Ill.; St. Louis University School of Medicine, 1950; interned at the St. Mary's Hospital in East St. Louis; died May 3, aged 39, of melanoma.

Gaebler, Arthur ⊕ St. Petersburg, Fla.; College of Physicians and Surgeons, Chicago, 1895; formerly practiced in Chicago, where he was on the staff of the Englewood Hospital; died May 15, aged 88, of hypertensive heart disease.

Greider, William Henry ⊕ Tulsa, Okla.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1911; died Feb. 28, aged 89.

Hartwell, Arthur Spear ⊕ Norwood, Mass.; Jefferson Medical College of Philadelphia, 1897; fellow of the American College of Surgeons; formerly medical examiner of Norfolk County; one of the founders of the Norwood Hospital; died Feb. 25, aged 85, of cerebral thrombosis.

Johns, William Alexander ⊕ Corinth, Miss.; Memphis (Tenn.) Hospital Medical College, 1894; formerly secretary of the Alcorn-Tishomingo Counties Medical Society; died June 7, aged 86, of carcinoma of the prostate.

Kilborn, Melville Graves, West Orange, N. J.; Jefferson Medical College of Philadelphia, 1930; member of the Medical Society of New Jersey; specialist certified by the American Board of Anesthesiology; member of the American Society of Anesthesiologists; on the staff of Orange Memorial Hospital; died in Livingston April 1, aged 51, of rheumatic heart disease.

Lum, Paul Albert, Whittier, Calif.; University of California Medical School, San Francisco, 1930; at one time health officer of Dos Palos; served during World War II; died in the Veterans Administration Hospital in Long Beach May 17, aged 53, of acute adrenal insufficiency, lobar pneumonia, and carcinoma of the stomach.

Lynn, Arthur Ray, Marshalltown, Iowa; State University of Iowa College of Medicine, Iowa City, 1905; past-president of the Marshall County Medical Society; on the staffs of the Evangelical Deaconess Home and Hospital and St. Thomas Mercy Hospital; died April 27, aged 71, of cerebral vascular accident with hemiplegia.

Mathews, William Joseph ⊕ Hoboken, N. J.; Medico-Chirurgical College of Philadelphia, 1900; for many years on the staff of St. Mary's Hospital; died May 31, aged 79, of arteriosclerotic heart disease.

Palmer, Robert Vickery ⊕ Avenue, Md.; University of Maryland School of Medicine, Baltimore, 1895; a trustee of St. Mary's Seminary Junior College, St. Mary's City; died in the University Hospital, Baltimore, Feb. 19, aged 83, of pneumonia.

Park, Irving Herman ⊕ Brookline, Mass.; Middlesex College of Medicine and Surgery, Waltham, 1937; served during World War II and won the Distinguished Service Cross; died in the New England Medical Center, Boston, May 30, aged 43, of cerebral vascular accident, thrombocytopenia, and acute myelogenous leukemia.

Payne, Redmond Wellington, San Francisco; Cooper Medical College, San Francisco, 1889; died April 18, aged 89.

Rivin, Henry Albert ⊕ Delano, Calif.; Jefferson Medical College of Philadelphia, 1919; served during World War I; died May 21, aged 58.

Robinson, W. Joseph ⊕ Creston, N. C.; University Medical College of Kansas City, Mo., 1904; died in the Ashe County Memorial Hospital in Jefferson April 26, aged 75, of heart disease.

Rost, Walter Franz H., New Paltz, N. Y.; Schlesische Friedrich-Wilhelms-Universität Medizinische Fakultät, Breslau, Prussia, Germany, 1923; honored with a presidential citation for his medical work with the local draft board; on the staffs of the Kingston and Benedictine hospitals in Kingston; died April 25, aged 55, of coronary thrombosis.

Savage, Philip Monroe ⊕ San Bernardino, Calif.; Cooper Medical College, San Francisco, 1907; fellow of the American Public Health Association and the American College of Surgeons; was superintendent of San Bernardino County Charity Hospital and on the staffs of St. Bernardine's and St. Bernardino County Charity hospitals; died May 31, aged 74, of carcinoma of the prostate.

Spann, Sylvester A., Meridian, Okla.; Meharry Medical College, Nashville, Tenn., 1914; died May 19, aged 73, of peritonitis.

Stephenson, George William ⊕ Coos Bay, Ore.; University of Oregon Medical School, Portland, 1951; interned at the Providence Hospital and served a residency at the University of Oregon Medical School Hospitals and Clinics in Portland; an associate member of the American Medical Association; died May 13, aged 38, as the result of an automobile accident.

Sullivan, Michael Joseph, Meriden, Conn.; Cornell University Medical College, New York City, 1900; formerly city health officer; on the staff of Meriden Hospital; died May 12, aged 78, of arteriosclerotic heart disease.

⊕ Indicates Member of the American Medical Association.

AUSTRIA

Phonocardiographic Changes After Operation for Mitral Stenosis.—At the meeting of the Society for Internal Medicine in Vienna on Feb. 17, Dr. W. Auinger reported that phonocardiograms made in eight patients with mitral stenosis before and after they had been operated on revealed characteristic changes that permitted evaluation of the operative success. These changes consisted of prolongation of the first heart sound and doubling of the interval between the first and second sounds, which after the operation were found to approach more nearly to normal. The respiratory curve proved to be a reliable aid in differentiating the mitral opening sound from a reduplication of the second heart sound and from the third heart sound, as it showed a change of the reduplication distance within the single respiratory phases but no change in the doubling of the interval.

Antihuman Globulin Deviation.—At the same meeting, Dr. C. Steffen stated that it is now possible to study with the aid of the Coombs test, the conglutination methods, the thrombocytes-Coombs test, and various methods of agglutination the occurrence of autoantibodies against erythrocytes, thrombocytes, and leukocytes. All these methods, however, use cell indicators, to which one binds the antigenic cell extracts, that indicate the course of an antigen-antibody reaction by an unspecific agglutination. Thus a reaction environment is produced that does not correspond with the immunobiological process in the body. Fixation of the antibodies in the tissue cells cannot be directly demonstrated by these methods.

The antihuman globulin deviation method, however, makes it possible to demonstrate in the same manner an antibody that has become fixed in blood and tissue cells, for example, an incomplete Rh-immune body in Rh-erythrocytes. The principle of this method consists in the incubation of lyophilized tissue or blood cells with a serum that is suspected to contain an antibody with a specificity against a substrate of the cells used. After incubation the cells are washed free from proteins under refrigeration, and the centrifuged cell pulp is mixed with a Coombs serum of known titer. After a certain deviation interval the mixture is centrifuged and the supernatant Coombs serum is retested for its activity. The testing of the activity of other Coombs' serum before and after the antihuman globulin deviation is made with O-Rh-erythrocytes that are loaded with a monovalent Rh-immune body of high titer. For control purposes incubation is always carried out with a normal serum in parallel with that of the serum obtained from the patient; the same amount of tissue substrate is incubated and subsequently a similar determination of the antihuman globulin deviation is made.

When antibodies are present in the serum, they saturate the tissue substrates in the course of the incubation. In a protein-free reaction environment the known antihuman globulin activity of the Coombs serum is reduced in the subsequent deviation by the fixed antibodies in the tissue substrate as a result of the human globulin property of these antibodies. This is shown by a loss of titer of the Coombs serum before and after the deviation by the experimental cells, while such a loss of titer does not occur in the control experiments with normal serum. The direct form of the method appears to be of such a type that with the cells of the patient himself an antihuman globulin deviation is carried out. The reliability of the method was first tested on erythrocytes that had been artificially saturated with incomplete antibodies, and the suitability of the method for demonstrating autonomous antibodies was ascertained. In immunothrombopenia and immunoneutropenia the antihuman globulin deviation method was tested and used successfully to demonstrate antithrombocyte and antileukocyte antibodies in the serums of patients. Lyophilized suspensions of thrombocytes and leukocytes were used as a saturated substrate.

In addition to Cavelti's experimental work, the antihuman globulin deviation was applied clinically to patients with polyarthritis and with rheumatic endocarditis. Control experiments showed that a lyophilized substrate is as efficient in producing saturation as a native substrate, and consequently the method can be used for routine diagnostic purposes. Mixtures of tissue from heart, muscle, capsular ligament, and cardiac and muscular tissues alone were used as substrates. Many serums obtained from patients with polyarthritis and rheumatism were studied and results showed an appreciable antihuman globulin deviation between the experimental and the control serum. This antihuman globulin deviation can be traced back only to the presence in the serum of rheumatic patients of a substance with the properties of human globulin that is specific with regard to the tissue used. This substance is believed to be an incomplete antibody. This concept has been confirmed by the results of absorption experiments. Furthermore the substance obtained from the serums of rheumatic patients, after being saturated specifically with the used substrates, could be broken off from the substrates, demonstrated in the eluates, and resaturated from the eluates on the substrates again. The antibody could be absorbed quantitatively from the serum of a rheumatic patient to the substrate that had been used for saturation. The serum, which had been taken off with a pipet after being saturated, behaved like a normal serum in the repeated saturation experiment.

It is concluded that the antihuman globulin deviation presents a method by which antibodies fixed to blood and tissue cells and the circulation of antibodies with a certain tissue specificity may be demonstrated in the serum. Because of the ease with which this method is carried out, it is suitable for routine diagnosis.

Resection of the Hip.—At a meeting of the Society of Physicians in Vienna Feb. 18, Dr. A. Sonnenschein emphasized that it is still too early for an evaluation of the plastic operation on the hip joint with the use of endoprostheses because of the possible later occurrence of deficiency of the used synthetic material or its limited bearing strength. Consequently resection of the head and occasionally also the neck of the femur and adjustment of the stump to the acetabulum is recommended. Follow-up examinations were made on 71 patients who underwent resection of the hip joint for chronic hip diseases. The results in 44 were good and in 27 poor. As compared with plastic operations on the hip joints using artificial epiphyses, the resection of the proximal end of the femur depends on the natural powers of healing, adjustment, and transformation.

Causes of Granulocytopenia.—At the same meeting Dr. H. Fleischhacker stated that the normal number of leukocytes depends on new formation in the bone marrow and the extent of the destruction in the peripheral blood. Central influences exert a regulatory influence. Granulocytopenias may be caused by impairment of the bone marrow; chemical, toxic, and infectious influences; and radium and roentgen irradiation. Among the forms of granulocytopenia characterized by a tumor of the spleen, the myeloscleroses with extramedullary formation of blood, hypersplenism, and splenic anemia must be distinguished. Differentiation is possible with the aid of sternal puncture and biopsy of the spleen. Granulocytopenias caused by allergic and autoimmune bodies are the result of a peripheral destruction of leukocytes. Leukocyte antibodies in a woman with cyclic agranulocytosis of five years' duration were demonstrated by blood transfusion into healthy persons and in vitro with the aid of leukocyte agglutination, the antihuman globulin test, and Finch's sedimentation test. The clinical manifestations improved markedly with splenectomy. Postoperatively menstruation was no longer associated with the occurrence of granulocytosis, but the granulocytes still showed the typical variations and the leukocyte antibodies remained unchanged. With regard to the treatment of agranulocytosis, transfusions of fresh blood are more

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

effective than those with preserved blood. After intramuscular injections of 10 cc. of cerebrospinal fluid obtained from healthy persons, pronounced leukocytosis may be produced in healthy persons and also in patients with granulocytopenias. This effect is mainly due to influencing the cell units by which leukocytes are broken up, thus prolonging the duration of life of the granulocytes in the circulation. In aplastic anemia and granulocytopenia the effect of blood transfusions can be greatly increased by also injecting spinal fluid, so that less blood is required and a prolongation of the effects may be achieved.

Surgical Closure of a Rectourethral Fistula.—At the meeting of the Austrian Society of Urology in January Dr. Uebelhör reported on the case of a man, 68 years of age, in whom a rectourethral fistula had developed after a prostatectomy. An abscess that was located on the dorsal side of the abdomen had been opened during the prostatectomy. A colostomy was made shortly after the prostatectomy, and only then did the extremely poor condition of the patient improve. Six months later the patient returned to the hospital for closure of the fistula. At this time a calculus the size of a plum stone was found in the posterior urethra, which intermittently closed the fistula. The surgical approach was through the perineum. The urethra was separated from the rectum, and the calculus was removed following dilation of the urethral fistula. Both fistular openings were sutured after the interposition of the levator. Several months later the colostomy was closed, and the patient has remained well.

BRAZIL

Intestinal Giardiasis.—The pathogenic significance of Giardia lamblia is still a matter of controversy. Although eminent gastroenterologists and parasitologists believe this parasite to be pathogenic in only a few children and adults, a growing number of pediatricians regard Giardia as a frequently pathogenic protozoan in children. Profiting by a relatively high incidence of giardiasis (11% in children under 15 years of age) in Porto Alegre, Dr. Estelle Budiansky reported in *O Hospital* (45:555, 1954) on a series of 117 children under 14 years of age whose stools showed Giardia (in almost all of these in the form of cysts). Asymptomatic carriers in childhood seem to be rare (only two in this series). The most common symptoms found in these children were repeated diarrhea, recurrent abdominal pains, loss of appetite, nausea, vomiting, and malnutrition. The celiac syndrome and such nervous symptoms as irritability, headache, dizziness, and disturbed sleep may be associated with giardiasis. The partial or total relief of the symptoms after treatment with an acridine derivative (Metoquin), coinciding with the disappearance of the parasites from the feces in 90% of the patients, suggests a causal relationship, although several other factors might have caused the symptoms and Giardia may have had only an aggravating effect. The author concludes that, whenever a child presents one or more of the symptoms mentioned and the stools are repeatedly positive for Giardia, the child should be treated with Metoquin, even in the presence of other causative factors. Whenever a child presents one or more of the symptoms mentioned and the stools are repeatedly negative, duodenal catheterization should be performed, and if this does not clarify the diagnosis treatment for giardiasis should be given.

Peridural Anesthesia.—Dr. Nelson Sá Earp, of the Santa Theresa Hospital of Petropolis, Rio de Janeiro, at a meeting of São Paulo surgeons, reported a series of 1,700 patients in whom peridural anesthesia was used. Among the advantages of this method are its safety; there were no deaths in this series. Death as a consequence of peridural anesthesia is only caused by technical errors, such as injecting the anesthetic solution into the intradural space. The absence of deaths, however, does not mean absence of minor accidents. Lipothymia occurred in about 7% of these patients. When it occurs, it comes at the end of the injection, causing a relaxation of the muscles and the drooping of the patient, as about 99% of the injections are made with the patient in the sitting position. If he is not laid down on the bed immediately a convulsive crisis develops. The reaction is believed to be due to cerebral ischemia, owing to the sitting position and emotional instability. For this reason Dr. Earp uses preanesthetic psychic preparation and thereby markedly reduces the rate of occurrence of this reaction. Patients in shock or with massive hemorrhage have been subjected to peridural anesthesia without any harmful effect; on the contrary, with the cessation of the pain the shock may be decreased. Another possible accident is the apnea caused by paralysis of the intercostal muscles, which occurred in two of the author's patients. In one of them artificial respiration had to be maintained for about 30 minutes. During this time the heart worked normally, and the patient recovered completely. The second patient was a cachectic older man in whom a gastroenterostomy had to be done. Artificial respiration was all he needed to recover completely, permitting the completion of the operation.

Death During Anesthesia.—Dr. F. F. Brusarosco in *Anais paulistas de medicina e cirurgia* (68:459, 1954) reported a series of 16 patients who died during anesthesia among 235 persons subjected to 242 thoracic operations. Only one of them was unconscious before the beginning of the anesthesia. The series included 48 operations on the heart and great vessels, 41 exploratory thoracotomies, 41 pneumectomies, 38 esophagogastric resections, 32 lobectomies and segmentectomies, 8 pulmonary decortications, 8 exereses of mediastinal tumors, 6 closures of bronchocutaneous fistulas, and 20 other operations such as vagotomies, sympathectomies, and extraction of foreign bodies. In the age group from birth to 19 years there were 51 patients with 6 deaths; in the group from 20 to 49 years, 135 patients with 8 deaths; and in the group over 50 years old, 49 patients with 2 deaths. Thus half of the deaths occurred in the group of better-risk patients, possibly because in the group over 50 years old many of the operations were limited to a simple exploratory thoracotomy, owing to the fact that the disease had reached an inoperable stage. The type of anesthesia used was as follows: cyclopropane-ether-curare 85 with 6 deaths, cyclopropane-ether 63 with 4 deaths, cyclopropane-nitrous oxide-curare 2 with 2 deaths, nitrous oxide-ether-curare 20 with 1 death, nitrous oxide-pentothal-curare 10 with no deaths, nitrous oxide-meperidine-curare 4 with no deaths, and nitrous oxide-intravenous procaine-meperidine-curare 58 with 3 deaths. The author believes that the type of anesthesia or the agent used was not the cause of the death but rather its injudicious use in the hands of insufficiently experienced anesthetists. Among 84 patients with uncontrolled or partially controlled respiration 9 deaths occurred; among 82 patients with the respiration controlled only during the intrapleural part of the operation 4 deaths occurred, and among 76 patients with controlled respiration throughout the operation 3 deaths occurred. Maneuvers that proved to be particularly dangerous included (1) placing the patient in the supine position, this procedure having caused a severe shock in 19 patients, with 2 deaths; (2) the changing of the endotracheal catheter during tracheotomy, which was tried in 2 patients, both of whom died; and (3) operative exploration of the mediastinum, which, performed in 9 patients, caused the death of 2 from intractable cardiac standstill.

ENGLAND

Annual Report of Council of the British Medical Association.—The annual report of the Council of the British Medical Association in the *British Medical Journal* (Supp., March 19, 1955) reports that, after the Minister of Health's statement that physicians would be asked not to prescribe certain proprietary preparations in cases where it had not been possible to reach satisfactory price arrangements with the manufacturers, the Council obtained an assurance from the Ministry that the Minister's announcement in no way departed from the agreed policy that a general practitioner is quite free to prescribe whatever he decides to be necessary in the best interests of his patient. The Council believes that it is unfortunate that the Minister opened his campaign by referring to a group of well-known proprietary antiasthmatics that, though more costly, were often more efficacious and better tolerated than the supposedly equivalent standard preparation.

Attention was drawn to the fact that, although now there is at least one general practitioner on every regional hospital board, the position with regard to teaching hospitals is far from satisfactory. For instance, in London on only 6 of the 12 boards of governors of teaching hospitals is a general practitioner included among the members. Steps are to be taken to remedy this state of affairs. Satisfaction was expressed at the financial success of *Family Doctor*, the popular health journal of the association. For the second year in succession it has been run at no cost to the association. *Family Doctor* has become the most widely quoted magazine in Great Britain.

In view of the large number of serious and fatal accidents in which motorcyclists receive head injuries, the Council has been trying to persuade the Commissioners of Customs and Excise to withdraw the purchase tax payable on crash helmets. It is estimated that only about 20% of civilian motorcyclists wear crash helmets. The membership of the association in the United Kingdom represents 71% of the total profession and 80% of the working profession. The Anglo-American and Anglo-Canadian Exchange Scheme, which enables a small number of physicians to visit the United States and Canada in exchange for visits to this country by American and Canadian physicians, has been continued. Five British physicians have visited the United States and Canada during the year.

The Council of the World Medical Association has reported to member-associations that the association is in serious financial difficulties, and it has proposed a substantial increase in the rate of subscription. The difficulties are mainly caused by the widening scope and increasing cost of its activities and by the fact that many national associations do not pay their full membership subscription. The British Medical Association Council has carefully considered how it can best help the World Medical Association. It is convinced that this organization serves a necessary purpose in presenting the views of the medical profession to international governmental bodies such as the World Health Organization and the International Labour Office, and, moreover, as the British Medical Association was largely responsible for the creation of the World Medical Association, the Council believes that it must do all in its power to ensure the World Medical Association's continuance. The Council has accordingly made an unconditional gift of £1,000 to the World Medical Association to help it over its immediate difficulties. It has also studied the World Medical Association's financial statements with a view to offering constructive advice. It has suggested to the World Medical Association Council that the crisis is serious enough to justify an immediate and thorough examination of its finances, organization, and activities and that, after effecting such economies as are practicable, its council should work out a program of activity within the revenue that it can reasonably expect to receive. It has recommended that the proposed increased rate of subscription should be reconsidered, partly because, if certain member-associations do not pay their full subscriptions even at the present rate, it is unlikely that they will pay any substantially higher rate.

Mass Radiography.—In Birmingham an x-ray service for general practitioners was inaugurated in 1949. A mass radiography center was established in an old building in the center of the city. Although no advertisement of the facilities appears in the press and there are no evening or Saturday morning sessions, during the five years about 11,000 persons voluntarily requested a roentgenogram of the chest. Dr. L. A. McDowell has published an analysis of the 3,371 persons (1,460 men and 1,911 women) who came to the center of their own accord during the 12 months, March, 1953, to February, 1954 (*Tubercle* 36:122, 1955). Although there were 14 persons under the age of 15 and 94 aged 60 or over, 68.5% were in the age group 15 to 34. In spite of the fact that in Birmingham chest x-ray facilities are readily available to physicians, 20% of those attending of their own accord were under the care of a general practitioner at the time. Just over 50% wanted the roentgenogram made as a routine check. Most of these were not under the care of a physician. A somewhat smaller number wanted a roentgenogram made because of symptoms; more than half of these were not under the care of a physician. The rest wanted a roentgenogram made because of contact with tuberculosis; most of these were not under the care of a physician.

Of the 3,371 persons examined, 63 had radiological evidence of pulmonary tuberculosis; 18 had healed calcified lesions; 9 had healed fibrotic lesions; and 36 were referred for further investigation. Of these 36 persons, 22 had active tuberculosis. This gives an incidence of active tuberculosis of 6.5 per thousand for the group, compared with the national finding for mass radiography examinees of 3 per thousand. Of these 22 active cases, only 2 patients were without symptoms, and 10 were in the age group 15 to 24. What is described as "the startling finding in this group of active cases" is that 16 patients had tubercle bacilli in the sputum. In 11, cavitation was clearly shown in the roentgenogram. The author concludes that patients with pulmonary symptoms should be encouraged to visit their family physicians and that all of them should have a roentgenogram of the chest. For many of them all that is required is a routine roentgenogram, and this can be most economically provided by a modification of the present mass miniature radiography service, whereby general practitioners are given free access to such facilities. The symptomless person who wants a routine check-up should also have the opportunity of having it at a mass radiography center without first consulting his physician. On the other hand, persons with symptoms should consult their physicians before being x-rayed.

More Patients than People.—According to the chairman of the London Executive Council of the National Health Service, before long there may be more people on London physicians' lists than there are inhabitants in the London County Council area. This is attributed to lack of identifying details and change of name. As an example of the difficulties encountered, a physician in the east end of London has a list containing more than 100 people named Singh, four of them with the first name, Piara. In India Piara Singh is as common as John Smith in the United Kingdom.

Effects of Nuclear Explosions.—The Minister of Health said that the total amount of radiation received by each resident in the United Kingdom is about 0.03 r, about one-third of the American figure. Even this amount is artificially high because it is calculated on the assumption that a man stands outside in the open for 24 hours a day for about 50 years, and because it also assumes that none of the activity weathers away from the surface of the ground. The dose of radiation that has been agreed on by an international commission as a maximum permissible level for workers on radioactive isotopes or for radiologists is 0.3 r per week or, taking working hours and holidays into account, about 15 r a year. Where a large population has to be considered, however, the number of genes at risk is greatly increased, and the number of matings that might conceivably carry harmful genes is also much increased. Estimates of the dose of radiation over a generation that is likely to double the spontaneous mutation rate have varied from 3 to 300 r. About 50 r in 25 years is as good an estimate of the upper limit of allowable exposure as can be made at present. Research in genetic changes is inevitably slow, but it is most unlikely that the increase in radioactivity that has occurred so far will have any appreciable genetic effect. Another government spokesman said that the use of atomic energy for civil purposes cannot possibly raise any danger to the public health. A slightly less reassuring attitude is adopted in an editorial of the *British Medical Journal* (March 26, 1955, p. 775), which concludes that we know far too little on this important subject and that an intense study of it is urgently needed. Although the radiation dose from the nuclear explosions carried out so far is too low to have caused much genetic damage, a continuation of the tests at the present scale over a period of many years might constitute a serious genetic hazard.

Sugar and Dental Caries.—Evidence that increased consumption of sugar has no significant effect on the development of dental caries in children is to be found in a report recently published under the aegis of the Medical Research Council (King, J. D.; Mellanby, M.; Stones, H. H., and Green, H. N.: The Effect of Sugar Supplements on Dental Caries in Children, Medical Research Council Special Report, no. 288). The report is based on a carefully controlled investigation of over 700 children, aged 2 to 14 years, in institutions in London, Liverpool, and Sheffield. The children were first observed for one year on their regular diet, in order to ascertain the natural caries increase. They were then divided into control and test groups; the latter were given an additional supplement of refined or raw sugar for periods of one to two years; and the incidence of caries was assessed in both groups at the end of this time. It was found that the children in Liverpool and Sheffield, whose ages ranged from 3 to 14 years, were receiving 466.5 to 730.9 gm. (15 to 23.5 oz.) of sugar a week in their regular diet. During the period of observation those in the test groups received a supplement of 684.3 gm. (22 oz.) of refined sugar per week. As the children in the London groups were aged only 2 to 4 years, and as their normal sugar intake ranged from 388.8 to 715.4 gm. (12.5 to 23 oz.) a week, it was decided that they would not be able to cope with a further 684.3 gm. a week. It was therefore decided that those in the control groups should receive about 342.1 gm. (11 oz.) a week, and those in the test groups were given 684.3 gm. of either white or brown sugar a week.

The results demonstrate that relatively great differences in the total sugar content of the diets of children in institutions had no significant effect on the initiation and spread of dental caries in periods of one to two years. As regards the deciduous teeth, there was, as a whole, no evidence that sugar as administered in this investigation resulted in any increase in caries. In the case of the permanent first molars, although the groups fed additional sugar tended to show a slightly greater increase in, and spread of, caries than the control groups, the total figures for these teeth did not disclose any consistently significant differences. A comparison of the London children receiving supplements of sugar showed a caries experience in those receiving brown sugar similar to that of those receiving white sugar and the controls.

Aging and Mental and Physical Capacity.—Prof. William Hobson in the May issue of the *Practitioner* states that in a random sample of old people living at home, 43% had a resting diastolic blood pressure of 100 mm. Hg or over and most of these were in good health. There is some evidence that the increasing deafness, especially for higher tones, that commonly increases with age may be due to acoustic trauma in industry. Although deafness is more common in elderly men, vertigo is more common in women, probably associated with arteriosclerosis of the labyrinth. The power of accommodation falls steadily with age until the age of 50, after which it remains stationary. The range of normality of serum alkaline phosphatase, serum cholesterol, and blood urea are all much higher than in younger age groups. In a series of 98 elderly men the range of serum cholesterol was 176 to 409 mg. per 100 ml. (mean 268); the corresponding figures for a series of 141 elderly women were 200 to 481 (mean 310). On the other hand, serum calcium, blood sugar, and hemoglobin levels appear to be little changed with age. In a random sample of relatively healthy people over pensionable age living at home (191 men and 282 women), about 29% of the men and 45% of the women suffered from some pathological condition that impaired mobility. Most of this was due to cardiovascular disease (48% of those disabled), joint conditions (13% of those disabled), and chronic bronchitis (13% of those disabled).

The available evidence lends no support to the idea of fixing 65 years of age for retirement from employment. One great need at the moment is for more refined tests that will measure intellectual capacity in the aged. The present tests do not measure many of the higher mental abilities, tend to discriminate against the elderly, and take no account of difficulties due to such physical disabilities as deafness and tremor. He notes that the retiring age for professors at Edinburgh University is 70, and at Oxford and Cambridge it has just been raised to 67. He concludes by suggesting that "perhaps one of the reasons why old ladies live so much longer than old men is that they never retire."

Welfare State.—In an address on the role of the individual in health service delivered before the British Hospitals Contributory Schemes Association, Lord Beveridge, author of the scheme on which the National Health Service is based, drew a sharp distinction between the "welfare state" and the "welfare society." He does not like the former term because "it gives to some people the idea that all that they need for welfare should be provided by the State and that all they have to do is to use their votes to get it from the State." He prefers the term "welfare society" because, although some things must be done by the state, much more has to be done by private citizens for themselves and in helping their neighbors. He gave some striking figures for the progress that the British Hospitals Contributory Schemes Association has made. The essence of these schemes is that people contribute in order to obtain certain benefits for themselves and their families over and above those available through the National Health Service. There are now 39 contributory schemes, with more than 3,500,000 members paying contributions ranging from 1 to 7 cents a week and producing a total annual income of 6,300,000 dollars. The contributors with their dependents number about 10 million people, or about 20% of all the people in Britain. This is an outstanding example of voluntary action refusing to be eradicated by a welfare state.

Accidental Poisoning.—According to the Registrar General's Statistical Review of England and Wales for 1951, in the period from 1931 to 1939, 130 children under 15 years of age died as a result of accidental poisoning. The comparable figure for the next decade was 277. In each period 79% of all the deaths occurred among children between 1 and 5 years. Deaths from aspirin poisoning in the two periods were 3 and 13, respectively, from ferrous sulphate and Fersolate 2 and 17, and from methyl salicylate 7 and 24. If all poisons and medicaments had been kept out of reach of these children, these deaths could have been prevented. In 1951, 820 people died from accidental poisoning; 264 from poisoning by solid and liquid substances; and 556 from poisoning by gas and other vapors. These figures are higher than in any of the preceding 10 years. Barbiturates were responsible for 117 of these deaths, compared with 33 in 1942; aspirin and salicylates were responsible for 27, compared with 10 in 1942, and other analgesics and soporifics for 21 (the same number as in 1942). Accidental poisoning occurred more commonly in the home than anywhere else: 50% involving barbiturates, 68% aspirin, and 82% other drugs.

Accidents in the Home.—An analysis of home accidents in England and Wales by C. A. Boucher (*Month. Bull. Min. Health* **14:** 49, 1955) shows that during the last 10 years 57,413 people have died as a direct result of an accident in the home, including about 10,000 children under 5 years of age. An analysis of the 1953 figures shows that 12% occurred in the age group from birth to 4 years, 2% from 5 to 14 years, 6% from 15 to 44 years, 11% from 45 to 64 years, and 69% 65 years and over. In other words, four-fifths of the fatal domestic accidents occur in children under 5 years of age and in people aged 65 and older. In children between the ages of 1 and 4 years, a fatal home accident is the third largest cause of death; the peak period of risk is during the third year of life. The most frequent types of fatal home accidents are: falls (60%), burns and scalds (10%), coal gas poisoning (10%), suffocation (9%), and poisoning (9%). An examination of the trend of these fatalities over recent years shows an increasing number of fatalities in older persons, an increasing number of deaths from falls, coal gas poisoning, and other poisoning, and a decrease in the number of deaths from suffocation and scalds.

Salmonella in Liquid Egg.—The Public Health Laboratory Service has published a report of an investigation to assess the importance of liquid egg as a possible vehicle of infection (*Month. Bull. Min. Health* **14:**65, 1955). Salmonella typhimurium and S. thompson are responsible for many cases of food poisoning. Of 1,649 samples of untreated or chilled liquid hen egg tested, 5 contained S. typhimurium, 3 contained S. pullorum, and 1 contained S. meleagridis. Of 65 samples of untreated or chilled liquid hen and duck egg mixture tested, 4 contained S. typhimurium. S. typhimurium was also isolated from 7 of 345 samples of frozen hen egg, from 1 of 59 samples of frozen duck egg, and from 17 of 55 samples of frozen hen and duck egg mixture. Of 106 samples of untreated or chilled imported hen eggs tested, one sample of an Irish mixture contained S. pullorum. One hundred fifteen samples of frozen imported hen eggs were tested. Of 80 Australian samples, 2 contained S. typhimurium and 15 S. pullorum. Of 25 Chinese samples, one contained S. thompson; and of one Danish, one Dutch, and eight Irish samples, none contained Salmonella organisms.

Sale of Sex Hormones.—Some time ago, in view of reports of the misuse of sex hormones for the suppression of lactation and the treatment of menopausal conditions, the British Medical

Association approached the Council of the Pharmaceutical Society to discuss whether any control should be imposed on their distribution and an inquiry was made as to the practice of dispensing such products without a prescription. As a result the council will advise pharmacists not to supply sex hormones or their preparations unless satisfied that the customer is obtaining them on medical advice, though not necessarily presenting a prescription. This does not apply to cosmetic preparations containing hormones which are being considered separately. The pharmaceutical journal, *Chemist and Druggist* (April 16, 1955, p. 433), says that the issue of such statements is attended by more evils than it is intended to reduce and should not be resorted to even for so laudable a purpose as to please the British Medical Association. There is no halfway house between control and noncontrol.

Sir David Bruce.—The centenary of the birth of Sir David Bruce has been commemorated by a special number of the *Journal of the Royal Army Medical Corps* (April, 1955). This contains a bibliography of his 170 publications. Bruce began his study of medicine at the University of Edinburgh at the age of 21 and graduated in 1881. In August, 1883, he received a commission in the Army Medical Service, and seven months later he was assigned to Malta, where he carried out his pioneer investigations on undulant fever. His first two papers announcing the discovery of what we now know as Brucella melitensis were published in the *Practitioner* (39:161, 1887; 40:241, 1888). In 1894 he was assigned to South Africa, where he began investigations that lead to the discovery of the trypanosome responsible for trypanosomiasis in man and animal and its mode of transmission by the tsetse fly. During World War I he completed his major contributions to medical knowledge by his work on trench fever and tetanus. He was the first Army medical officer to be elected a fellow of the Royal Society of London.

Price of Pharmaceuticals.—The Ministry of Health has just completed an investigation into the earnings of secondary manufacturers, compounders, and wholesale distributors of drugs. The investigation was based on a sample of 19 companies with an annual turnover of about 67,200,000 dollars, and the accounts for three successive financial years were examined. In a letter to the Association of British Pharmaceutical Industry, the Ministry states that the results of the cost investigation do not suggest that the general level of prices that manufacturers receive for unbranded standard drugs and preparations is excessive and that there is no occasion for health departments to seek to influence the level of prices received by manufacturers for unbranded standard drugs and preparations or the earnings that are being obtained in wholesale distribution.

Loneliness and Mental Health.—In Edinburgh, admission to mental hospitals are higher among people from the Highlands or from foreign countries than among the Edinburgh-born, according to Prof. F. A. E. Crew in an address to a conference on preventive aspects of mental health work. This is in line with evidence from the United States, Norway, and London that admission rates to mental hospitals are appreciably higher among immigrants than natives and among the unmarried, the widowed, and the divorced than the married. He concluded that the common factor is loneliness or cultural isolation. If mental health is to be preserved, a person should be attached to something that gives a satisfying purpose to his activities and yields security.

Industrial Museum Renamed.—The Industrial Museum of the Ministry of Labour has been renamed the Industrial Health and Safety Centre. The Centre, the only one of its kind in Great Britain, is a permanent exhibition of methods, arrangements, and appliances for promoting safety, health, and welfare in industry. It is open daily, free of charge, and guides are always on duty to conduct parties of visitors and to answer questions. In 1953 there were over 12,000 visitors. The name was changed because of the increasing emphasis that is now laid on industrial health. The Centre, which has a unique and up-to-date collection of exhibits, many lent by manufacturers, deals with industrial diseases, first aid, safety devices, lighting, ventilation, sanitation, and decorating of factory premises.

Neglect of Smallpox Vaccination.—The Minister of Health has expressed concern at the current neglect of vaccination except as an emergency measure during outbreaks of smallpox. The present position is that in England and Wales, in 1954, only 34.5% of the infants under the age of one year were vaccinated. This is far below what may be regarded as satisfactory. It is urged that every healthy infant be vaccinated. The revaccination of children within two or three years of first entering school not only maintains or revives their individual protection but also facilitates the control of local outbreaks of smallpox. It also insures that any further vaccination in later life will be less likely to have any serious reactions or complications.

Army Pathology Service.—The centenary of the Army Pathology Service is being celebrated by a special dinner at the Headquarter Mess of the Royal Army Medical Corps at Millbank, London. After the Crimean War Florence Nightingale urged the formation of an Army medical school, but it was not until 1860 that this was finally opened. Among the notable names associated with the school were those of Wright, Bruce, Leishman, and Cummins. Fundamental work on the cause and prevention of Malta fever, the isolation of the causative organism of kala-azar, and the work in Uganda on African sleeping sickness, culminating in the discovery of the causative organism, was done by members of the staff.

Poliomyelitis in an Isolated Community.—The simultaneous isolation of two immunologically distinct types of poliomyelitis virus from a single sample of feces obtained from a healthy one-year-old child is reported by Macrae and Shepherd (*Month. Bull. Min. Health* 14:55, 1955). In all, 73 samples of feces from residents of a relatively isolated community in Scotland were investigated, and this was the only successful isolation of poliomyelitis virus. The viruses were fully virulent when inoculated intracerebrally into monkeys. Poliomyelitis had not been diagnosed clinically within living memory in the community in which the child lived.

Radioactive Sterilization of Food.—During investigations (Food Investigation Special Report no. 61) in which foods were irradiated with 2 mev., it was found that, when the food was subjected to a dosage sufficient for efficient sterilization, changes in flavor, color, or texture nearly always occurred. Although these effects could be minimized with the use of special techniques such as deaeration or freezing of the food before irradiation, they could not be completely eradicated. The results of these experiments make it seem doubtful that sterilization of food by these means will prove commercially satisfactory.

Physician as Postmaster-General.—Among the changes in the Cabinet announced by Sir Anthony Eden on his appointment as Prime Minister was that of Dr. Charles Hill as Postmaster-General. Until his election as a Member of Parliament, Dr. Hill was Secretary of the British Medical Association.

FRANCE

Smallpox.—The epidemic that raged over France from the end of 1954 to the beginning of 1955 originated chiefly in Vannes, the capital of Morbihan. It was started by a soldier on leave from Saigon who was vaccinated a month before coming back to France and did not present any sign of the disease. A prefectorial decree made it compulsory to send smallpox patients to a hospital for isolation. Such severe forms as confluent smallpox, hemorrhagic smallpox, and variolar nephritis were observed in this epidemic. Abortive forms were common in those who had been vaccinated shortly before acquiring the disease or during the incubation period. Fifteen of the 70 patients in this epidemic died. Most of these were sick or infirm before they acquired smallpox. Compulsory vaccination proved to be the most effective measure used to stop the epidemic. Immunization of the staff in the hospital and the physicians proved insufficient as five hospital workmen, two interns, and seven physicians contracted the disease. One physician who was revaccinated in 1942 and again on Jan. 3, 1955, died 48 hours after his first contact with a smallpox patient. A revaccination of the staff in the hospital and of all physicians every three years is recommended.

Electrophoretic Variations in Serum.—G. Lagrue in the *Vie Medicale* for Dec. 12, 1954, shows that early in some acute infections such as pneumonia there is an increase in the alpha globulin; in some subacute infections such as tuberculosis and typhoid the gamma globulin increases. In the course of tuberculosis and acute articular rheumatism an increase in alpha globulin occurs. In a patient with pulmonary tuberculosis an increase in gamma globulin is associated with a bad prognosis. In lipid nephrosis there is a decrease in serum albumin and gamma globulin and an increase in alpha globulin. All nephropathies with marked albuminuria are associated with an increase in alpha globulin. In cirrhosis of the liver there is a decrease in alpha globulin but a marked increase in beta and gamma globulin. Arterial atheroma is associated with a moderate increase in beta globulin.

Regeneration of Tissue in Man.—Prof. R. Leriche in the *Bulletin of the International Society of Surgery* for January, 1955, stated that scar tissue can impede tissue regeneration. For example, in the case of nervous tissues the myelinic or amyelinic nerve fibers pervade the scar and this anarchic proliferation gives way to a neuroma. Although regenerative potential is present, it is vitiated. In bone, osteogenic cells may remake an epiphysis or a diaphysis, but the regeneration is functional and not anatomic. It is impossible to remake a joint but we can ossify the ligamentous insertions. The author concludes that tissues make a great effort toward regeneration but that it is often frustrated.

Death of Professor Gougerot.—Prof. H. Gougerot, the famous dermatologist, died at the age of 64. He contributed studies of sporotrichosis, cutaneous tuberculosis, leprosy, and the role of allergy in eczema.

INDIA

Tuberculous Ulcer of the Stomach.—M. S. Kanvinde in the *Indian Practitioner* (8:309 [March 3] 1955) stated that tuberculous ulcers of the stomach are rarely found in spite of the high incidence of pulmonary tuberculosis. A 20-year-old man came to the hospital complaining of pain in the epigastrium of one year's duration. The pain had become progressively worse and usually followed the ingestion of food. It was relieved by vomiting. There was no history of hematemesis or melena. There was tenderness on deep pressure in the right side of the epigastrium. Clinically there were no signs of pulmonary tuberculosis. The sedimentation rate was 110 mm. Stools showed the presence of cysts of Endamoeba histolytica. Gastric analysis showed marked hyperchlorhydria with 90 units of free hydrochloric acid and 100 units of total acidity. The tuberculin test with old tuberculin (OT) 1:500 was negative. A gastrointestinal series revealed a hyperplastic stomach. The duodenal cap filled with difficulty. After 8 hours the stomach was half full; after 24 hours it was one-fourth full. A radiological diagnosis of pyloric stenosis was made. A roentgenogram of the chest showed a soft opacity in the infraclavicular region bilaterally.

On operation, the pyloric end of the stomach was seen to be markedly thickened. Regional lymph nodes were enlarged and palpable. Pyloric carcinoma was suspected and a partial gastrectomy was performed removing the thickened portion and the lymph nodes. Recovery after operation was uneventful. The specimen showed two irregular ulcers in the pyloric region on the anterior and posterior walls situated almost opposite each other. The floor of the ulcers was covered with necrotic material. The borders of the ulcer were swollen and irregular. The serosal surface did not show any tubercles. On section the regional lymph nodes showed soft yellow-gray areas of caseation. Histological examination of the ulcer margin showed a thickened mucosa infiltrated with lymphocytes forming several tubercular follicles with epithelioid cells and Langhan's type of giant cells. The ulcer crater was deep and lined by granulomatous tissue consisting of epithelioid cells and giant cells. The base of the ulcer did not show any fibrous tissue. Lymph nodes had the characteristic appearance of tuberculous lymphadenitis. No acid-fast bacilli were seen.

Treatment of Leprosy.—S. Sinha in the *Indian Journal of Medical Sciences* (9:124 [March 3] 1955) reported the treatment of 700 persons with leprosy, 25% of whom had the nodular type of the disease (nine of these had a positive lepromin reaction with ocular involvement); 15% had the neural type (five of these had polyneuritis with trophic ulcers); and 60% were of the mixed type. Cutaneous biopsy was positive for Mycobacterium leprae in 60% of the patients and 30% were diagnosed on clinical findings only. The sedimentation rate varied between 15 and 60. The treatment consisted of streptopas, vitamin B, Thiosemicarbarsone, and iron preparations. Erythrocyte counts and hemoblobin estimations were done every eighth week. A diet consisting of plenty of milk, fruits, and proteins was advised. All patients were encouraged to continue their vocation. Measures were taken to prevent spread in the family. Other members of the family, especially children, were given BCG vaccination. Resolution in nodular lesions was found to commence after the 10th injection of streptopas, and the improvement continued in varying degree in most patients. Some required a second course of streptopas after a rest of one month. The improvement in patients with the neural type was very satisfactory but in those with the mixed type the clinical response was variable. Perforating ulcers were the quickest to respond to this treatment. Keratitis and iridocyclitis showed a better response to this therapy than to that with other drugs. Bleeding from the nose and ulcers in the nose responded quickly and completely. If cutaneous and nasal smears could be done, reduction in the bacilli in the cutaneous smears from 200 to 300 organisms per field to 2 to 10 per field was observed within 130 days. Nasal smears were found to be negative after the third injection. Toxic reactions were not common. More recently it has been found that streptotibine gives better results.

Serpasil and Coagulation of Blood.—M. G. Khirwadkar in the *Indian Journal of Medical Sciences* (9:160 [April 4] 1955) stated that about 14 alkaloids have been isolated from the root of Rauwolfia serpentina. The empirical formula of reserpine, one of these, differs markedly from that of the rest. In common with the whole root it produces hypotension, bradycardia, and sedation. A 32-year-old man was admitted to a hospital for malignant hypertension. He was given two tablets of reserpine and 30 mg. of phenobarbital three times daily. After about three weeks, venesection was performed to relieve dyspnea. The next morning it was noticed that the blood removed from the patient's vein the evening before had not clotted. In order to find out whether the delay in clotting was due to the action of the drugs the patient was receiving, 5 cc. of blood was removed from 12 other patients in the ward who were not receiving the same drugs. To four of these samples reserpine (Serpasil) was added; to another four, phenobarbital alone was added; and to the remaining four, both were added. The second group showed clotting but the first and third did not. In another patient who was being treated with reserpine the prothrombin and clotting times were found to be prolonged but the bleeding time and platelet count were normal.

Hemangioma of the Orbit.—Gantayat and Bhaskarrao in the *J. Indian M. A.* (24:596 [May 1] 1955) reported the case of a 25-year-old woman who was admitted for a painless prominence of the left eye of four years duration. The swelling was gradually increasing. A proptosis of her left eyeball of 1.5 cm. was observed. Movements of this eyeball were limited in all directions. Her preauricular lymph nodes were enlarged on both sides. The vision in her right eye was 6/10 and in her left eye was almost absent. Her optic disk appeared pale and the margins were blurred; the arteries and veins were tortuous. A biopsy was performed and the sections revealed fibroangiomatous tissue. There was no evidence of malignancy. Evisceration of the left orbit was performed. Examination of the mass removed showed a soft conical tumor arising from the retro-orbital tissues. On section a number of cavernous spaces filled with blood were observed. On microscopic examination, large cavernous blood spaces lined by endothelium and bound together by trabecular connective tissue were seen. There was no evidence of malignancy.

Ascorbic Acid Removal from Adrenal Glands.—Mukherji and Werner in the *Bulletin of Calcutta School of Tropical Medicine* (3:19 [Jan. 1] 1955) reported that ascorbic acid is removed from the adrenal gland by the action of corticotropin or some specific factor called adrenal ascorbic factor and such depletion occurs in response to stress, epinephrine, atropine, physostigmine, and adrenergic blocking drugs. Rauwolscine, which is the alkaloid of Rauwolfia canescens, is a strong adrenergic blocking drug and experiments were performed to find out whether ascorbic acid was removed from the adrenal glands of rats after administration of Rauwolscine. The left adrenal gland was removed for control estimation. Rauwolscine was injected intraperitoneally and the right adrenal gland was removed immediately after killing the rat one hour after injection. Control animals were treated similarly using isotonic saline solution instead of Rauwolscine. It was found that a significant removal of ascorbic acid from the adrenal gland occurred after the administration of Rauwolscine.

ISRAEL

Health in Israel.—In 1954 the number of physicians in Israel was 3,828 compared to 3,717 in 1953. The ratio of physicians to population is now 1:440, which is one of the highest in the world. In Great Britain it is 1:960; in France 1:1,200; in Austria and Switzerland 1:700; and in Norway 1:950. Eighty per cent of Israel's physicians work in towns, about 2,400 in the three main cities alone (Jerusalem, Haifa, and Tel Aviv), so that about 65% of the physicians are serving 45% of the population. More than 30% of the physicians immigrated to Israel after the establishment of the state in 1948, but more than 90% of the total number of Israeli physicians had practiced medicine in their countries of origin before immigration. The 50 members of the faculty of Hadassah Medical School are graduates of about 50 universities from 16 different European countries, the Americas, Asia, and Africa. Every group of immigrant physicians brought along the knowledge and habits of the countries of their origin or the universities where they were trained. The Jewish population, numbering 650,000 in May, 1948, has absorbed 750,000 new immigrants (35% from Asia, 15% from North Africa, and 49% from Europe). This uncontrolled immigration has few precedents in modern history. Of the community of Yemenite Jews numbering 47,000, who were transferred to Israel by air in the course of one year, 16,000 were in need of hospitalization on arrival. A moderate estimate shows that about 20,000 patients with schistosomiasis have been imported into Israel with immigrants from Yemen and Iraq. Sixty per cent of the immigrants from North Africa are afflicted with trachoma. The large number of tuberculous patients among the new arrivals compelled the state to increase the number of tuberculosis hospital beds from 590 in 1949 to 1,986 by the end of 1952. The transfer of whole communities from Asia and North Africa caused the infant mortality rate to rise from 29:1,000 in 1947 to 51:1,000 in 1949, but, as a result of intensified activities in this field, the rate dropped to 34.5:1,000 in 1954. The ratio between the occurrence of infant toxicosis among new immigrants and established residents was 17:1. The mental and social adjustment of these heterogeneous groups (a gap of eight centuries separates the immigrant from Western Europe from his contemporary from the Yemen) constitutes an enormous medicosocial task. Fifty per cent of the physicians are over 50 years old; 600 have already reached the age of 65 or more and must be replaced in the next few years. Taking into account that the average number of graduates of the medical school is about 60 each year, it will take 10 years just to provide the replacements needed. Moreover, there is a shortage of specialists, especially in radiology, anesthesiology, orthopedics, general surgery, ophthalmology, and psychiatry. The lack of well-trained specialists in public health and preventive medicine will certainly make itself felt in the coming years when the reorganization and expansion of the existing health services are undertaken.

New Outbreak of Schistosomiasis.—While during 1953 and 1954 isolated cases of schistosomiasis could be observed in new immigrants, now for the first time infestation with Schistosoma hæmatobium has been discovered in a group of settlers in the Jordan Valley. G. Wittenberg and Z. Saliternik reported (*Harefuah*, vol. 48, May 15, 1955) that Bulinus, the snail vector of S. hæmotobium, is widespread. In addition to the natural foci, it has appeared in ponds and drainage canals constructed within the past two years. In view of radical changes in distribution of artificial water courses occurring lately, its appearance and disappearance is unpredictable. On the other hand, the distribution of Planorbis, the snail vector of Schistosoma mansoni, is limited to a small section of the Yarkon River. This unequal distribution of snail species is inverse to the frequency of human carriers of corresponding Schistosoma parasites; the numerous carriers of S. mansoni (mainly immigrants from Yemen) are in contrast to the rare carriers of S. hæmatobium. This is the main reason why new cases of schistosomiasis are rare. However, in view of the ubiquity of snail carriers of either species, outbreaks of schistosomiasis are to be expected and precautions are advised. Recent discovery of urinary schistosomiasis at Tirat-Zvi, a village in the Jordan Valley, indicates that an epidemic development of that disease may occur, if every possible precaution is not taken to stop its course immediately. At present nearly 50% of the youth of this village are infected.

MEXICO

Pleuropneumonia and Urethritis.—The fact that the micro-organisms of the pleuropneumonia group produce diverse pathological pictures in animals has been known for some time. Because they have been found in the human genitourinary tract, it has been suggested that they may have some relation to Reiter's disease. Olarte has recently (*Revista de investigación clinica*, vol. 7, April-June, 1955) isolated seven species of the pleuropneumonia group from seven men with chronic urethritis in whom the presence of Neisseria gonorrhoeae was eliminated by the use of ordinary bacteriological methods. Urine and urethral secretions were taken from 12 patients. The urinary sediment and urethral secretion were mixed with a drop of diazine solution (2 mg. per milliliter). This preparation was cultured on a solid infusion medium of fresh heart muscle with peptone at a pH of 7.8. To this was added 30% sterile horse serum. In order to avoid desiccation, the Petri dishes were sealed with clay. They were incubated at 30 C and were observed at 48-hour intervals with a stereoscopic microscope. Minute colonies or small masses were observed. The incubation was continued for 20 days before discarding the negative cultures.

From seven of the patients, organisms with the characteristics of the pleuropneumonia group were isolated. It was possible to make serial cultures from the positive cultures. It was also possible to promote their growth in a liquid medium without the appearance of bacterial forms. This last requisite is important because it has been found that the L forms of bacterial origin, which are similar to the micro-organisms of the pleuropneumonia group, can be differentiated because they fail to grow in liquid mediums and, if they do, they convert to the bacterial form from which they spring.

One of the species was inoculated into the chorioallantoid membrane of the chick embryo, and it was possible to recover this same species from the embryo. In preparations stained with Giemsa's stain, numerous inclusion bodies were observed. The author states that he is not trying to establish a relationship between the findings of a positive pleuropneumonia group organism with the urethritis that the seven patients had but that he is simply demonstrating the existence of these micro-organisms in Mexico. The pathogenicity of these micro-organisms in man is still to be established.

Control of Yellow Fever.—Although no cases of jungle yellow fever have been observed in Mexico, if the necessary precautions are not taken it is believed that within a year and a half there will be cases of this disease in the states and territories bordering Guatemala, because a northward spread of the disease has been in progress ever since the epidemic outbreak in Panama in 1948. For this reason the federal government has taken the following measures: (1) vaccination of all inhabitants of Campeche and Yucatán first and then those of Chiapas, Tabasco, and Quintana Roo; (2) intensification of the campaign against the mosquito; and (3) instruction to the public on the preventive measures that can be taken individually.

CORRESPONDENCE

SURGICAL ANESTHESIA AGAIN

To the Editor:—In the April, 1954, issue of *Surgery*, I had an editorial on surgical anesthesia. In the Dec. 25, 1954, issue of THE JOURNAL, page 1628, a letter of mine entitled "Surgeon and Anesthetist—Good and Bad Teamwork" was published. In both of these contributions I pointed out that suture lines are occasionally broken by patients struggling under anesthesia. This is not a theoretical consideration, as I have seen it occur before the wound was closed. How often suture lines break after the wound is closed, when the patient struggles under anesthesia, no one knows. My entire purpose was to point out an occurrence that, while probably not frequent, is a lamentable incident for the patient when it does occur, and to indicate that such incidents could be cut to the minimum, or probably entirely eliminated, by a closer cooperation between the anesthetist and the surgeon. Certainly the welfare of the patient is in jeopardy if there is not close cooperation between these two specialists who must work so closely in unison. The best anesthesiologists with whom I am acquainted and with whom I have corresponded agree with the thesis I put forward. Indeed, the professor of anesthesiology in one of the leading medical schools on this continent wrote: "I agree with you entirely that the conditions about which you complain are bad for the patient and inexcusable on the part of the anesthesiologist. I believe that this is an example of how badly we fulfill our duties as physicians when we become addicted to routine practice rather than individual appraisal of a therapeutic procedure. . . . I intend to bring your very stimulating letter to the attention of my students."

Although my object was to stimulate closer cooperation between the surgeon and the anesthesiologist, several anesthesiologists seem to resent my suggesting that there could possibly be an improvement in their specialty. It goes without saying that there can be improvement in all of our specialties. Every physician should be glad to have any suggestion that furthers the welfare of the patient. One anesthesiologist, Dr. Willis G. Watrous (*Surgery* 36:831, 1954) made the statement that my editorial in *Surgery* "cannot go unchallenged by the anesthesiologists." This chip-on-the-shoulder attitude does not enhance the working cooperation between the surgeon and the anesthetist, which I was seeking to bring about. The statements I made were factual statements and included episodes encountered in my own experience. They are fortunately not the rule, but the exception. What we are playing for, however, is the 100th case. We cannot attain that goal by antagonistic attitudes, but only by the closest and the most wholehearted cooperation. Dr. Watrous further says that considering the functions of the anesthetist, "it is inconceivable that many patients will be carried lightly to the point of straining with handicap to the work of the surgeon." This is certainly a naïve point of view, as every experienced surgeon knows. It is true that such incidents are decreasing with the improvement in surgical anesthesia, but it is only by recognizing present shortcomings that we can continue our improvement.

Dr. Watrous (*J. A. M. A.* **157**:843 [March 5] 1955) and others (Helmsworth, F. W.: *J. A. M. A.* **157**:945 [March 12] 1955. Greene, B. A., and Berkowitz, S.: ibid. **157**:1433 [April 16] 1955) discuss other causes of postoperative hernias than wound disruption. Every surgeon is well aware of the various causes of these unhappy conditions. I was discussing only one cause, which the anesthetist can aid the surgeon in eliminating.

I wish to reiterate that the procedure of sucking out the trachea is greatly overdone, and this should not be done at all if it is going to cause the patient to struggle. Some anesthetists claim that their reason for doing this is to get the patient to cough. That is much better done after the patient is conscious. There are certain calculated risks that go with surgery. It is much better to run the risk of a little atelectasis than to destroy the work the surgeon has done by causing the patient to struggle violently before he is conscious. After he is conscious, pain will keep him from any movement that will do damage to his wound. It is true that morphine postoperatively depresses the respiration somewhat, but that is another calculated risk that the surgeon has to take. It is much better to give the patient a narcotic and let him sleep his anesthesia off than to let him struggle it off. I agree with Beecher (*J. A. M. A.* **157**:242 [Jan. 15] 1955) that only hypnotics and not narcotics should be given preoperatively. Then if the patient needs a narcotic postoperatively, it will not depress his respiration so much. One ample dose of a narcotic given soon after operation to prevent struggling is often all the patient needs. Once he is awake, all the various methods of improving his respiratory function may be used.

Again let me repeat that nothing I said in either of my previous contributions was meant as an adverse or blanket criticism of anesthesiologists. On the contrary, my experience with anesthesiologists has been such as to lead me, in general, to give them the highest praise. I was only pointing out some unfavorable things that are occasionally encountered and that all of us, both surgeons and anesthesiologists, should strive to correct.

WASHINGTON'S BASIC SCIENCE LAW

To the Editor:—Our attention has been directed to a paragraph relating to Washington state's new basic science law appearing in the May 28, 1955, issue of THE JOURNAL. This paragraph, which was printed in table 35, on page 303, begins as follows:

> Washington
>
> By recent amendment, effective June 8, 1955, examination may be waived if the applicant has passed an examination before examiners in the basic sciences in those states that have a basic science act, *or before examiners authorized to issue licenses to practice the healing art in another state*. (Italics are ours.)

The following statement is taken from the new law: "(43.74.035 RCW, 1a) The applicant has passed an examination in the basic sciences before examiners in basic sciences in those states which have a basic science act." This is a basic condition for reciprocal license in the basic sciences, and nowhere in the law is there any statement that would permit the Washington basic science board to accept a medical, osteopathic, chiropractic, drugless, or chiropody certificate as a substitute for the basic science certificate implied in the quotation given above. Ever since the law passed the 1955 legislature, this office has been deluged with requests for applications to obtain basic science registration by reciprocity. Besides answering these letters we have informed the professional societies in the state of the actual situation in regard to the new law, but the facts of the case have evidently not spread as fast as the false rumors. Therefore, we believe it may be of value to present the registrants of other states, who make up the bulk of our inquirers, with a fuller and more accurate account of the new law.

The law took effect at midnight June 8. The board thereupon commenced a thorough study of the laws, regulations, and examinations of the other basic science boards in the country. You will note that the law makes several specifications, in the waiver section, as to the states whose registrants may be accepted by the Washington board. These specifications will require individual consideration and exercise of judgment on the part of the board. As the members of the board are faculty members with full-time teaching schedules, they will be unable to devote all their energies to this task. It is estimated that no final decisions may be made before the January, 1956, examination period.

EDWARD C. DOHM

Department of Licenses
Olympia, Wash.

GOVERNMENT SERVICES

ARMY

Civilian Medical Care for Army Personnel.—Medical care and treatment is provided for Army personnel in the United States generally by dispensaries, infirmaries, and hospitals located at military installations throughout the country. There are many locations, however, where Army or other U. S. federal medical treatment facilities are not available. In such cases the services of civilian physicians, clinics, and hospitals are necessary. Certain criteria and procedures define the conditions under which individuals of the Army may be authorized civilian medical care at the expense of the Army. Civilian medical care, other than elective, is authorized for commissioned officers, warrant officers, enlisted personnel, cadets of the U. S. Military Academy, and prisoners, when these personnel are on a duty status or when they are absent from their place of duty on other authorized nonduty status. Payment for civilian medical expenses incurred by Army personnel who are absent without leave is not authorized.

Army personnel are authorized civilian medical care only when there are no military or other federal medical treatment facilities available; first aid or emergency treatment is authorized at any time. In this connection, emergency medical care may be defined as that which is required to save life or limb, or that which prevents great suffering. Surgical operations should not be performed without prior approval of the surgeon of the nearest military installation or the appropriate military authority listed below, unless indicated as an emergency procedure. Elective medical treatment by civilian physicians will not be authorized. Medical care of dependents of military personnel from civilian sources at Army expense is not authorized. Dependents of military personnel may obtain available medical care at Department of Defense medical facilities only. Any obligations resulting from civilian medical care to dependents of military personnel are the responsibility of the dependents concerned or their sponsors.

As a general rule military authorities will furnish the civilian medical agency with prior written approval for ordinary medical care to Army personnel under their jurisdiction. In such cases prior arrangements with the civilian medical agency will be made by the individual or by a proper military authority. For emergency cases treated without prior written authorization, the commanding officer of the patient's organization and the surgeon of the Army area in which the treatment is rendered, as listed below, should be immediately notified by the civilian medical agency, giving the individual's name, organization, military address, nature of illness or injury, and statement of the practicability of transfer of the patient to an Army or other governmental hospital. The civilian agency or physician then will be advised without delay by the appropriate military authorities as to procedures to be followed. Bills for medical care and treatment of Army personnel who have presented authorization or have received emergency treatment should be submitted to the commanding officer of the organization to which the patient belongs or to the military authority who provided the authorization for the medical service. If these addresses cannot be determined, the bill should be sent to the military authorities listed below.

For Services Rendered in the Following States	Submit Bills to
First Army Area	
Connecticut	The Surgeon, First Army; Governors Island, New York, N. Y.
Maine	
Massachusetts

The bill should show the full name, rank, and service number of the patient and his organization. The place and inclusive dates of treatment, diagnosis, and itemized charges must be entered on the statement. The lack of this information seriously impairs prompt payment by the Army. The duty status of the patient at the time of illness or injury, such as duty, leave, or pass, should be included, if known. Payment will be further expedited if the following certificate is typed on the bill and signed:

> I certify that the above charges are correct and just; that payment therefor has not been received; that the services were necessary in the care and treatment of the person named above; that the services were rendered as stated; and that the charges do not exceed those customarily charged in this vicinity.

____________________ ____________________

(Signature of Payee) (Business Title or Capacity)

Answers to specific questions or further information concerning this matter may be requested of the military surgeons at the above addresses or from The Surgeon General, Department of the Army, Washington 25, D. C. Any difficulties that are experienced should be called to the attention of these Army authorities in order that this program may function smoothly toward the best interests of the patient as well as the claimant.

Personal.—Lieut. Col. Edward J. Dehné, former chief of preventive medicine, U. S. Army, Caribbean, has been named by the surgeon general head of the Army environmental health laboratory at the Army Chemical Center, succeeding Col. Joseph H. McNinch, who is now serving in the office of the surgeon general, Washington, D. C.——Col. Robert L. Callison has been appointed chief of the preventive medicine division in the surgeon general's office. He was certified as a diplomat by the American Board of Preventive Medicine and Public Health, and for the past two years he has headed the environmental control and sanitation branch of the preventive medicine division.

Postgraduate and Graduate Courses for Physicians

Postgraduate Continuation Courses for Physicians—Sept. 1, 1955, to Aug. 31, 1956—Continued

17. HEMATOLOGY

Course Code No.	Title of Course	Location of Course	Type	Designed For	Total Hours	Methods of Instruction	Starting Date	Time Arrangements	Fee in Dollars
17 P 01261	Clinical Hematology [92]	University of Colorado School of Medicine 4200 E. Ninth Ave., Denver 20	S	S	45	Laboratory work Clinical case work	7/56	C; 6 days	75
17 P 01710	Clinical Hematology [5, 58]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	20	Laboratory work Clinical case work	9/21/55	I; 2 hr. weekly for 10 wk. Wednesdays	100
17 P 01711	Clinical Hematology [5, 58]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	20	Laboratory work Clinical case work	3/21/56	I; 2 hr. weekly for 10 wk. Wednesdays	100
17 P 01610	Hematology [5, 28]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	30	Laboratory work Clinical case work	6/11/56	C; 1 wk.	100
17 P 01753	Hematologic Diagnosis [58]	Michael Reese Hospital 29th Street and Ellis Avenue, Chicago 16	S	B	80	Laboratory work Clinical case work	7/18/56	C; 2 wk.	150
17 P 01831	Postgraduate Course on Hematology [307]	State University of Iowa College of Medicine Iowa City	R	B	6	Lecture or panel	11/10/55	C; 1 day	10
17 P 01873	Hematology [40, 27]	University of Kansas Medical Center 39th and Rainbow Blvd., Kansas City 12, Kan.	S	B	14	Laboratory work Demonstration	3/15/56	C; 2 days	30
17 P 02168	Diseases of Blood and Blood-Forming Organs [67]	Dept. of Postgraduate Medicine, University of Michigan Medical School University Hospital Ann Arbor, Mich.	R	B	34	Laboratory work Lecture or panel	4/56	C; 5 days	50
17 P 02845	Med PM 66—Clinical Hematology [58]	Montefiore Hospital East Gun Hill Road, New York 67	R	B	48	Laboratory work Clinical case work Lecture or panel	9/13/55	I; 3 hr. weekly for 16 wk. Tuesdays	75
17 P 02846	Med PM 67—Advanced Hematology [93]	Montefiore Hospital East Gun Hill Road, New York 67	R	B	40	Laboratory work Clinical case work Lecture or panel	9/20/55	I; 2½ hr. weekly for 16 wk. Tuesdays	75
17 P 02629	Hematology PM 31—Hematology	Mt. Sinai Hospital Fifth Avenue and 100th Street, New York	R	G	24	Laboratory work	11/ 1/55	I; 3 hr. weekly for 8 wk. Tuesdays	50
17 P 03326	5436-A Hematology [8]	New York University Post-Graduate Medical School 550 First Ave., New York	S	B	35	Lecture or panel Demonstration	11/ 7/55	C; 5 days	75
17 P 01337	Med PM 66—Clinical Hematology [58]	Montefiore Hospital East Gun Hill Road, New York 67	R	B	48	Laboratory work Clinical case work Lecture or panel	1/31/56	I; 3 hr. weekly for 16 wk. Tuesdays	75
17 P 01336	Med PM 67—Advanced Hematology [93]	Montefiore Hospital East Gun Hill Road, New York 67	R	B	40	Laboratory work Clinical case work Lecture or panel	2/ 7/56	I; 2½ hr. weekly for 16 wk. Tuesdays	75
17 P 02628	Hematology PM 30—Laboratory Methods in Hematology [88]	Mount Sinai Hospital Fifth Avenue and 100th Street, New York	R	G	64	Laboratory work	2/27/56	C; 4 wk.	200
17 P 02630	Hematology PM 32—Laboratory Methods in Blood Banks [88]	Mt. Sinai Hospital Fifth Avenue and 100th Street, New York	R	G	24	Laboratory work	4/ 3/56	I; 4 hr. weekly for 6 wk. Tuesdays	50
17 P 03297	546-A Clinical Hematology [9]	New York University Post-Graduate Medical School 550 First Ave., New York	S	B	20	Lecture or panel Demonstration	4/10/56	I; 2½ hr. weekly for 8 wk. Mondays, Thursdays	40
17 P 02961	Hematology DM1086	New York Medical College, Flower and Fifth Avenue Hospitals 1 E. 105th St., New York	R	G	20	Laboratory work Small group discussion	Anytime	I; 2½ hr. weekly for 8 wk. Tuesdays	50
17 P 03909	Clinical and Laboratory Hematology [190]	Bryn Mawr Hospital Bryn Mawr, Pa.	S	B	240	Laboratory work Lecture or panel	10/ 1/55	C; 6 wk.	200
17 P 03911	Clinical and Laboratory Hematology	Graduate School of Medicine, University of Pennsylvania Philadelphia	S	B	240	Laboratory work Lecture or panel	12/ 1/55	C; 6 wk.	200
17 P 03912	Clinical and Laboratory Hematology	Graduate School of Medicine, University of Pennsylvania Philadelphia	S	B	240	Laboratory work Lecture or panel	2/ 1/56	C; 6 wk.	200
17 P 03816	Hematology [31, 5]	Albert Einstein Medical Center, Northern Division York and Tabor roads, Philadelphia 41	R	G	25	Clinical case work Lecture or panel	Spring, 1956	I; 2½ hr. weekly for 10 wk. Wednesdays	75

17 P 03913	Clinical and Laboratory Hematology	Graduate School of Medicine, University of Pennsylvania Philadelphia	S	B	210	Laboratory work Lecture or panel	1/ 1/56	C; 6 wk.	200
17 P 03921	Practical Pediatric Hematology [101, 100]	The Children's Hospital 1740 Bainbridge St., Philadelphia	R	B	21	Small group discussion Lecture or panel	6/56	C; 3 days	60
17 P 01176	Clinical Pathology [13, 200]	The University of Texas Postgraduate School of Medicine, Temple Division, Scott and White (Clinic) Hospitals Temple, Texas	R	G	88	Laboratory work	Arranged	Specially arranged for 2 wk.	25

18. INDUSTRIAL MEDICINE

18 P 01913	Industrial Medicine [94]	Tulane University School of Medicine 1430 Tulane Ave., New Orleans	R	B	16	Lecture or panel	4/12/56	C; 2 days	25
18 P 03281	483-A Industrial Medicine for Physicians [31]	New York University Post-Graduate Medical School 550 First Ave., New York	S	B	280	Lecture or panel Seminars	9/26/55	C; 8 wk.	250
18 P 03285	482-B Industrial Hygiene Laboratory [95]	New York University Post-Graduate Medical School 550 First Ave., New York	S	G	Unknown	Laboratory work	9/55	Specially arranged	66
18 P 03287	4810-A Industrial Toxicology [58]	New York University Post-Graduate Medical School 550 First Ave., New York	S	B	Unknown	Lecture or panel Demonstration	9/55	Specially arranged	66
18 P 03282	481-A Medical Aspects of Compensation [96]	New York University Post-Graduate Medical School 550 First Ave., New York	S	B	35	Lecture or panel	10/31/55	C; 1 wk.	Unknown
18 P 03289	486-A Air Pollution [31]	New York University Post-Graduate Medical School 550 First Ave., New York	S	G	70	Lecture or panel	11/28/55	C; 2 wk.	60
18 P 03290	480-A Introduction to Radiological Safety [97]	New York University Post-Graduate Medical School 550 First Ave., New York	S	G	70	Lecture or panel	1/ 9/56	C; 2 wk.	60
18 P 01511	5133—A Tutorial Course in Internal Medicine [8, 101]	New York Postgraduate Medical School 550 First Ave., New York	S	G	6 mo.	Laboratory work Clinical case work	1/56	C; for 4 mo. or 6 mo.	100 mo.
18 P 03284	482-A Industrial Hygiene [31]	New York University Post-Graduate Medical School 550 First Ave., New York	S	G	Unknown	Laboratory work Lecture or panel	2/56	Specially arranged	66
18 P 03286	489-A Chemical Methods in Industrial Hygiene [98]	New York University Post-Graduate Medical School 550 First Ave., New York	S	G	Unknown	Laboratory work	2/56	Specially arranged	81
18 P 03288	4811-A Special Topics in Industrial Hygiene Laboratory Methods	New York University Post-Graduate Medical School 550 First Ave., New York	S	G	Unknown	Laboratory work Small group discussion	Unknown	Specially arranged	Unknown
18 P 03141	Course for General Practitioner	New York Polyclinic Medical School and Hospital 345 W. 50th St., New York 19	R	G	32	Laboratory work Clinical case work	Arranged	Specially arranged	100
18 P 03600	Seminar in Industrial Health [5, 77]	N. C. Memorial Hospital Chapel Hill, N. C.	R	B	12	Lecture or panel	2/ 9/56	C; 2 days	10
18 P 03681	Seminars in Industrial Medicine [52]	Institute of Industrial Health, College of Medicine, University of Cincinnati Cincinnati	S	B	50	Clinical case work Lecture or panel	9/10/55	I; 1 hr. twice weekly for 8 mo. Fridays, Saturdays	Unknown
18 P 03680	Occupational Skin Problem [11]	Institute of Industrial Health, College of Medicine, University of Cincinnati Cincinnati	S	B	35	Clinical case work Lecture or panel	10/10/55	C; 1 wk.	75
18 P 03682	The Lead Problem in Industry [41]	Institute of Industrial Health, College of Medicine, University of Cincinnati Cincinnati	S	B	30	Lecture or panel	11/ 7/55	C; 5 days	75
18 P 03971	Occupational Medicine [102]	Graduate School of Public Health, University of Pittsburgh Pittsburgh 13	R	S	220	Laboratory work Lecture or panel	11/21/55	C; 10 wk.	200
18 P 03995	Seminar on Industrial Medicine	Medical College of South Carolina 16 Lucas St., Charleston, S. C.	S	B	7	Lecture or panel	Unknown	C; 1 day	Nil

19. INFECTIOUS DISEASE

19 P 03516	Infectious Diseases [5]	University of Buffalo School of Medicine 3435 Main St., Buffalo	R	G	7	Clinical case work Small group discussion	12/ 1/55	C; 1 day	15

42 P 01217	Diseases of the Chest (Including Pulmonary and Cardio-Respiratory Diseases)[297]	Roosevelt Hotel Pittsburgh	R	B	16	Lecture or panel	10/ 2/55	I; 4 hr. weekly for 4 wk Sundays	Unknown
42 P 01470	Ninth Annual Postgraduate Course in Diseases of the Chest[230, 53]	Hotel Bellevue Stratford Philadelphia	S	B	40	Lecture or panel	3/56	C; 5 days	75
42 P 04134	Chest Diseases[292, 5]	The University of Texas, Southwestern Medical School 5323 Harry Hines Blvd., Dallas, Texas	R	G	14	Lecture or panel	5/56	C; 2 days	5
42 P 04183	Diseases of the Chest[13, 206]	The University of Texas Postgraduate School of Medicine, Temple Division, Scott and White (Clinic) Hospitals Temple, Texas	R	G	88	Laboratory work Small group discussion	Arranged	Specially arranged	25
	43. RADIOLOGY								
43 P 01089	Roentgen Diagnosis and Roentgen Therapy[64]	College of Medical Evangelists 1720 Brooklyn Ave., Los Angeles 33	R	G	31	Small group discussion Demonstration	10/ 4/55	I; 1 hr. weekly for 31 wk. Tuesdays	100
43 P 01223	882: (A) The Essential Physics of Therapeutic Radiology and (B) Clinical Applications of Radioactive Isotopes	University of Southern California School of Medicine 2025 Zonal Ave., Los Angeles 33	S	S	24	Lecture or panel	Spring, 1956	I; 2 hr. weekly for 12 wk. Mondays	75
43 P 01296	Radiology 302—Introduction to X-Rays and Radioisotopes	Yale University School of Medicine 333 Cedar St., New Haven, Conn.	S	S	12	Lecture	9/29/55	I; 1 hr. weekly for 12 wk.	25
43 P 01303	Radiology 304—Radioactivity	Yale University School of Medicine 333 Cedar St., New Haven, Conn.	S	S	30	Laboratory work Lecture or panel	3/15/56	I; 3 hr. weekly for 10 wk. Thursdays	100
43 P 01302	Radiology 303—X-Ray Physics	Yale University School of Medicine 333 Cedar St., New Haven, Conn.	S	S	20	Laboratory work Lecture or panel	5/ 1/56	I; 2 hr. weekly for 10 wk.	25
43 P 03838	American Roentgen Ray Society —Instructional Courses[105, 106]	Palmer House State Street, Chicago	R	S	6	Small group discussion Lecture or panel	9/20/55	C; 4 days	1.50
43 P 04601	Diagnostic Roentgenology[5, 58]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	40	Laboratory work Clinical case work	9/21/55	I; 4 hr. weekly for 10 wk. Wednesdays	100
43 P 01658	Course I—Diagnostic Radiology[5, 117]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	68	Laboratory work Clinical case work	10/ 3/55	C; 2 wk.	125
43 P 01668	The Clinical Uses of Radioisotopes[5, 130]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	60	Laboratory work Clinical case work	10/10/55	C; 2 wk.	200
43 P 03489	Instructional Courses[235, 236]	Palmer House Chicago	R	S	76½	Lecture or panel	12/11/55	Specially arranged	15
43 P 01659	Course I—Diagnostic Radiology[5, 117]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	68	Laboratory work Clinical case work	1/ 9/56	C; 2 wk.	125
43 P 01660	Course I—Diagnostic Radiology[5, 117]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	68	Laboratory work Clinical case work	2/27/56	C; 2 wk.	125
43 P 04602	Diagnostic Roentgenology[5, 58]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	40	Laboratory work Clinical case work	3/21/56	I; 4 hr. weekly for 10 wk. Wednesdays	100
43 P 01671	The Clinical Use of Radioactive Iodine[5, 130]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	30	Laboratory work Clinical case work	4/ 2/56	C; 1 wk.	100
43 P 01661	Course I—Diagnostic Radiology[5, 117]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	68	Laboratory work Clinical case work	5/ 7/56	C; 2 wk.	125
43 P 01669	The Clinical Uses of Radioisotopes[5, 130]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	60	Laboratory work Clinical case work	5/ 7/56	C; 2 wk.	200

		S. Wood St., Chicago 12			--	Laboratory work Clinical case work	5/21/56	C; 1 wk.	100
	Course 2—Clinical Radiology [5, 21]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	50	Laboratory work Clinical case work	Arranged	C; 2 wk.	70
43 P 01663	Course 2—Clinical Radiology [5, 21]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	100	Laboratory work Clinical case work	Arranged	C; 1 wk.	125
43 P 01664	Course 3—X Ray Therapy [5, 21]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	30	Laboratory work Clinical case work	Arranged	C; 1 wk.	60
43 P 01665	Course 3—X-Ray Therapy [5, 21]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	60	Laboratory work Clinical case work	Arranged	C; 2 wk.	110
43 P 01666	Course 3—X-Ray Therapy [5, 21]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	120	Laboratory work Clinical case work	Arranged	C; 4 wk.	200
43 P 01667	Course 3—X-Ray Therapy [5, 21]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	R	B	210	Laboratory work Clinical case work	Arranged	C; 8 wk.	300
43 P 01911	Radiologic Considerations of Pulmonary, Urological and Bone Disease [101]	Tulane University School of Medicine 1430 Tulane Ave., New Orleans	R	B	16	Lecture or panel Demonstration	11/17/55	C; 2 days	25
43 P 01869	Radiology and Radioactive Isotopes [187]	University of Kansas Medical Center 39th and Rainbow Blvd., Kansas City 12, Kan.	S	B	24	Clinical case work Lecture or panel Demonstration	2/13/56	C; 4 days	45
43 P 02032	Pediatric Radiology [187, 310]	Children's Hospital 300 Longwood Ave., Boston	S	S	125	Laboratory work Clinical case work	Arranged	Specially arranged for 1 wk.	150
43 P 02033	General Radiology 1 [187, 310]	Peter Bent Brigham Hospital 721 Huntington Ave., Boston	S	S	125	Laboratory work Clinical case work	Arranged	Specially arranged for 1 wk.	150
43 P 02035	General Radiology 2 [15, 310]	Massachusetts General Hospital Fruit Street, Boston	S	S	125	Laboratory work Clinical case work	Arranged	Specially arranged for 1 wk.	150
43 P 02036	General Radiology 3 [187, 310]	Boston City Hospital 818 Harrison Ave., Boston	S	S	125	Laboratory work Clinical case work	Arranged	Specially arranged for 1 wk.	150
43 P 02169	Diagnostic Radiology [41]	Dept. of Postgraduate Medicine, University of Michigan Medical School University Hospital Ann Arbor, Mich.	R	B	20	Lecture or panel	4/56	C; 5 days	50
43 P 02307	Radiology for Specialties [33, 5]	University of Minnesota Center for Continuation Study Minneapolis 14	R	S	32	Lecture or panel	11/ 7/55	C; 1 wk.	40
43 P 02320	Radiology for General Physicians [33, 5]	University of Minnesota Center for Continuation Study Minneapolis	R	G	16	Lecture or panel	4/ 9/56	C; 3 days	25
43 P 03382	651-A Diagnostic Radiology for General Practitioners [58]	New York University Post-Graduate Medical School 550 First Ave., New York	S	G	61	Lecture or panel	9/28/55	I; 2 hr. weekly for 32 wk. Wednesdays	100
43 P 03157	Roentgen Interpretation	New York Polyclinic Medical School and Hospital 345 W. 50th St., New York 19	R	G	480	Laboratory work Clinical case work	10/ 3/55	C; 12 wk.	300
43 P 03159	Advanced Diagnostic Roentgenology and Radiotherapy	New York Polyclinic Medical School and Hospital 345 W. 50th St., New York 19	S	B	480	Laboratory work Clinical case work	10/ 3/55	C; 12 wk.	300
43 P 02677	Radiology PM 80—Roentgenographic Interpretation of the Diseases of Bones and Joints	Hospital for Joint Disease 1919 Madison Ave., New York	R	G	26	Lecture or panel Demonstration	10/ 5/55	I; 2 hr. weekly for 13 wk. Wednesdays	150
43 P 03381	650-A Isotopes and Their Medical Application [95]	New York University Post-Graduate Medical School 550 First Ave., New York	S	B	72	Laboratory work Clinical case work	10/ 5/55	I; 2 hr. weekly for 36 wk. Wednesdays	250
43 P 02699	Radiology PM 41—Clinical Use of Radioactive Isotopes [150]	Mount Sinai Hospital Fifth Avenue and 100th Street, New York	S	S	100	Laboratory work Lecture or panel	10/ 6/55	I; 3 hr. weekly for 8 mo. Thursdays	200
43 P 02695	Radiology PM 30—Introduction to Nuclear Radiation Physics [8]	Mount Sinai Hospital Fifth Avenue and 100th Street, New York	S	S	45	Laboratory work Lecture or panel	10/12/55	I; 1½ hr. twice weekly for 15 wk. Wednesdays, Thursdays	100
43 P 02072	Radiology PM 31—Radiology of the Chest [108]	Mount Sinai Hospital Fifth Avenue and 100th Street, New York	R	G	10½	Clinical case work Lecture or panel	10/17/55	C; 7 days	50

7 G 069	S32: Cardiology and Vascular Disease [338, 357, 5, 143, 182]	Los Angeles County Hospital 1200 N. State St., Los Angeles 33	B & C	B	1664	Laboratory work Clinical case work	7/55	C; 12 mo.	1000
7 G 074	Electrocardiography [143, 5, 349, 428, 52]	University of Colorado School of Medicine 4200 E. Ninth Ave., Denver 20	B & C	B	28	Lectures and panels	9/20/55	C; 12 wk.	79
7 G 501	Electrocardiography [143, 5, 340, 428, 52, 38]	Denver General Hospital Denver	B & C	B	28	Lectures and panels	1/15/56	C; 12 wk.	79
7 G 230	Cardiovascular Disease [310, 143, 5, 331, 130, 16]	Massachusetts General Hospital Fruit Street, Boston	B & C	B	Unknown	Laboratory work Clinical case work	10/ 3/55	Specially arranged for 12 mo.	800
7 G 231	Cardiology 1 [310, 113, 331, 16, 28]	Beth Israel Hospital 330 Brookline Ave., Boston	B & C	B	Unknown	Laboratory work Clinical case work	1/30/56	Specially arranged for 3 mo.	500
7 G 688	Basic Course in Electrocardiography [173]	University of Oklahoma School of Medicine 800 N. E. 13th St., Oklahoma City	B	B	44	Laboratory work Small group discussion	3/ 5/56	C; 1 wk.	75
7 G 749	Cardiology [320, 16, 5, 143]	Graduate School of Medicine, University of Pennsylvania Philadelphia	B & C	B	1280	Laboratory work Clinical case work	9/26/55	C; 8 mo.	1000
		8. DERMATOLOGY							
8 G 120	Course 3—Dermatology [5, 329, 205]	Cook County Graduate School of Medicine 707 S. Wood St., Chicago 12	C	B	1500	Laboratory work Clinical case work	By appointment	C; 12 mo.	1000
8 G 232	Dermatology and Syphilology [310, 143, 5, 331, 87, 16]	Massachusetts General Hospital Fruit Street, Boston	B & C	B	Unknown	Laboratory work Clinical case work	10/ 3/55	Specially arranged for 12 mo.	800
8 G 819	525-B Dermatology and Syphilology (Graduate Course) [143, 5, 418, 16, 417]	New York University Post-Graduate Medical School 550 First Ave., New York	C	B	1500	Laboratory work Clinical case work	10/ 1/55	C; 12 mo.	400
8 G 820	525-C Dermatology and Syphilology (Graduate Course) [143, 5, 110, 16]	New York University Post-Graduate Medical School 550 First Ave., New York	C	B	1500	Laboratory work Clinical case work	10/ 1/55	C; 12 mo.	200
8 G 969	525-A Dermatology and Syphilology (Graduate Course) [143, 5, 329, 16, 117]	New York University Post-Graduate Medical School 550 First Ave., New York	B & C	B	1500	Laboratory work Clinical case work	10/ 1/55	C; 12 mo.	815
8 G 915	Dermatology and Syphilology [348, 320, 5, 113]	New York Polyclinic Medical School and Hospital 345 W. 50th St., New York 19	B & C	B	7728	Laboratory work Clinical case work	10/ 3/55	C; full time for 3 yr.	500
8 G 914	Dermatology and Syphilology [348, 320, 5, 143]	New York Polyclinic Medical School and Hospital 345 W. 50th St., New York 19	B & C	B	7728	Laboratory work Clinical case work	4/ 1/56	C; full time for 3 yr.	500
8 G 516	525-A Dermatology and Syphilology (Graduate Course) [143, 5, 329, 16, 417]	New York University Post-Graduate Medical School 550 First Ave., New York	B & C	B	1500	Laboratory work Clinical case work	7/ 1/56	C; 12 mo.	815
8 G 517	525-B Dermatology and Syphilology (Graduate Course) [143, 5, 418, 16, 417]	New York University Post-Graduate Medical School 550 First Ave., New York	C	B	1500	Laboratory work Clinical case work	7/ 1/56	C; 12 mo.	400
8 G 518	525-C Dermatology and Syphilology (Graduate Course) [143, 5, 410, 16]	New York University Post-Graduate Medical School 550 First Ave., New York	C	B	1500	Laboratory work Clinical case work	7/ 1/56	C; 12 mo.	200
8 G 408	Dermatology GM 1-A—Advanced Dermatology [128, 143, 330]	Columbia-Presbyterian Medical Center 630 W. 168th St., New York	B & C	S	Arranged	Laboratory work Clinical case work	Arranged	Specially arranged for 6 or 12 mo.	300 for 6 mo.
8 G 407	Dermatology GM 1—Clinical Dermatology [330, 143]	Columbia-Presbyterian Medical Center 630 W. 168th St., New York	B & C	S	Arranged	Laboratory work Clinical case work	Arranged	Specially arranged for 6 or 12 mo.	300
8 G 750	Dermatology [371, 16, 329, 5, 143]	Graduate School of Medicine, University of Pennsylvania Philadelphia	B & C	B	1280	Laboratory work Clinical case work	9/26/55	C; 8 mo.	1000
		9. ENDOCRINOLOGY							
9 G 076	Endocrinology [143, 5, 349, 428]	University of Colorado School of Medicine 4200 E. Ninth Ave., Denver 20	B	B	24	Lectures and panels	2/56	C; 12 wk.	Varies
		11. FORENSIC MEDICINE							
11 G 520	531-A Forensic Medicine (Graduate Course) [16, 5, 329, 113]	New York University Post-Graduate Medical School 550 First Ave., New York	B	B	1260	Laboratory work Small group discussion	9/26/55	C; 9 mo.	815

13. GASTROENTEROLOGY

13 G 751	Gastroenterology [18, 16, 329, 5, 143]	Graduate School of Medicine, University of Pennsylvania Philadelphia	B & C	B	1280	Laboratory work Clinical case work	9/26/55	C; 8 mo.	1000
13 G 068	814: Gastroenterology [122, 357, 182, 143, 5]	Los Angeles County Hospital 1200 N. State St., Los Angeles 33	B & C	B	1664	Laboratory work Clinical case work	9/55	C; 12 mo.	1000
13 G 067	851: Gastrointestinal Endoscopy [107, 357, 5, 182]	Los Angeles County Hospital 1200 N. State St., Los Angeles 33	B & C	B	832	Laboratory work Clinical case work	Arranged	C; 6 mo.	500

14. GENERAL MEDICINE

14 G 078	Applied Medical Science [143, 5, 340, 16, 430, 431]	Fitzsimons General Hospital Denver	B	S	56	Small group discussion Lectures and panels	9/ 5/55	C; 25 wk.	Varies
14 G 075	Gastrointestinal Physiology, Disease [143, 5, 340, 428]	University of Colorado School of Medicine 4200 E. Ninth Ave., Denver 20	B	S	28	Lectures and panels	3/56	C; 14 wk.	Varies
14 G 274	General Medicine [143, 329, 52]	The Department of Postgraduate Medicine, University of Michigan Medical School University Hospital, Ann Arbor, Mich.	B	B	850	Laboratory work Clinical case work	10/ 3/55	C; 9 mo.	500
14 G 718	Basic Medical Sciences [206, 16, 329, 5]	Graduate School of Medicine, University of Pennsylvania Philadelphia	B	B	1280	Laboratory work Small group discussion	9/26/55	C; 8 mo.	1000
14 G 911	Postgraduate Course in Medicine [5, 435, 58]	Montreal General Hospital and Royal Victoria Hospital 687 Pine Ave., West, Montreal, Canada	B & C	S	180	Clinical case work Small group discussion	7/ 1/56	I; 5 hr. daily, 6 days wk. for 6 wk.	225
14 G 900	Master of Science in Medicine [16, 423, 340]	Queen's University, Faculty of Medicine Kingston, Ontario, Canada	B	B	1 yr.	Laboratory work Lectures and panels	9/12/56	C; 10 mo.	200
14 G 166	Bachelor of Science (Medicine) [102, 16, 377, 391]	University of Toronto Toronto, Canada	B	B	Specially arranged	Laboratory work Small group discussion	7/ 1/56	Specially arranged	205
14 G 901	Advanced Graduate Course in Medicine [340, 34]	Faculty of Medicine, University of Toronto Toronto, Canada	B & C	B	210	Small group discussion Lecture and panel	8/22/56	C; 6 wk.	200

16. GYNECOLOGY

16 G 939	Postgraduate Anatomy, Obstetrics and Gynecology [414, 415]	University of Alabama Medical Center 1919 Seventh Ave., South, Birmingham 3, Ala.	B	S	128	Laboratory work Small group discussion	9/20/55	Specially arranged for 36 wk.	Unknown
16 G 171	Basic Science in Obstetrics and Gynecology [143, 423, 340, 16]	New York Medical College, Flower and Fifth Avenue Hospitals 1 E. 105th St., New York 29	B & C	B	8 mo.	Clinical case work Small group discussion	10/10/55	C; 8 mo.	710
16 G 752	Gynecology-Obstetrics [370, 16, 329, 5, 143]	Graduate School of Medicine, University of Pennsylvania Philadelphia	B & C	B	1280	Laboratory work Clinical case work	9/26/55	C; 8 mo.	1000
16 G 912	Post-Graduate Course in Obstetrics and Gynecology [5, 130, 100]	Royal Victoria, Montreal Maternity Hospital 687 Pine Ave., West., Montreal 2, Canada	B & C	S	180	Small group discussion Lectures and panels	8/15/56	I; 5 hr. daily, 6 days wk. for 6 wk.	225
16 G 904	Advanced Graduate Course in Gynecology [340, 34]	Faculty of Medicine, University of Toronto Toronto, Canada	B & C	B	240	Small group discussion Lecture and panel	8/22/56	C; 6 wk.	200

18. INDUSTRIAL MEDICINE

18 G 250	Industrial Health [16, 102, 349]	Harvard University School of Public Health 55 Shattuck St., Boston	B	B	2 mo.	Lectures and panels Demonstrations	2/ 6/56	C; 2 mo.	300
18 G 935	Industrial Medicine [336, 337, 338, 16, 143]	University of Rochester School of Medicine and Dentistry 260 Crittenden Blvd., Rochester 20, N. Y.	B & C	B	60	Laboratory work Small group discussion	9/19/55	C; 16 mo.	Unknown
18 G 519	481-A Industrial Medicine (Graduate Course) [100, 16, 5, 143]	New York University Post-Graduate Medical School 550 First Ave., New York	C	B	960	Laboratory work Clinical case work	9/26/55	C; 12 mo.	815
18 G 658	Industrial Medicine [143, 5, 333, 16, 100]	Institute of Industrial Health, College of Medicine, University of Cincinnati Cincinnati	B & C	B	1600	Laboratory work Clinical case work	7/ 5/56	C; 12 mo.	400
18 G 659	Industrial Medicine [143, 334, 335, 16, 100]	Institute of Industrial Health, College of Medicine, University of Cincinnati Cincinnati	B & C	B	2880	Laboratory work Clinical case work	7/ 5/56	C; 36 mo.	Fellowship stipend
18 G 789	Occupational Health [143, 313, 320, 16, 344]	Graduate School of Public Health, University of Pittsburgh Pittsburgh 13	B & C	B	3 yr.	Laboratory work Clinical case work	9/20/55	C; 34 mo.	700 per yr.

Graduate Courses for Physicians—Sept. 1, 1955, to Aug. 31, 1956—Continued

Course Code No.	Title of Course	Location of Course	Type	Designed For	Total Hours	Methods of Instruction	Starting Date	Time Arrangements	Fee in Dollars
18. INDUSTRIAL MEDICINE—Continued									
18 G 790	Occupational Health [143, 341, 329, 16, 183]	Graduate School of Public Health, University of Pittsburgh, Pittsburgh 13	B	B	10 mo.	Laboratory work Small group discussion	9/20/55	C; 10 mo.	700
18 G 468	Industrial Hygiene [440, 441, 16, 426]	University of Toronto, Toronto 5, Canada	B & C	B	960	Laboratory work Small group discussion	9/19/55	C; 32 wk.	425
20. INTERNAL MEDICINE									
20 G 070	830: Internal Medicine [216, 16, 357, 5, 143, 182]	Los Angeles County Hospital, 1200 N. State St., Los Angeles 33	B & C	B	1661	Clinical case work Small group discussion	9/55	C; 12 mo.	1000
20 G 077	Radiology Physics and Medical Use of Isotopes [143, 5, 349, 16, 429]	University of Colorado, School of Medicine, 4200 E. Ninth Ave., Denver 20	B	S	56	Laboratory work Small group discussion	9/55	C; 28 wk.	Varies
20 G 080	Fluid and Electrolyte Balance [143, 5, 349, 428]	University of Colorado, School of Medicine, 4200 E. Ninth Ave., Denver 20	B	B	32	Lectures and panel	9/55	C; 16 wk.	79
20 G 229	Internal Medicine 1 [310, 143, 5, 331, 16, 332]	Boston City Hospital, 818 Harrison Ave., Boston	B & C	B	Unknown	Laboratory work Clinical case work	9/ 1/55	Specially arranged for 12 mo.	800
20 G 803	5429-A Internal Medicine (Graduate Course) [143, 5, 329, 16, 34]	New York University Post-Graduate Medical School, 550 First Ave., New York	B & C	B	1100	Clinical case work Small group discussion	9/26/55	C; 12 mo.	815
20 G 471	Basic Science in Internal Medicine [143, 423, 349, 16]	New York Medical College, Flower and Fifth Avenue Hospitals, 1 E. 105th St., New York 29	B & C	B	8 mo.	Laboratory work Clinical case work	10/10/55	C; 8 mo.	710
20 G 521	5429-A Internal Medicine (Graduate Course) [143, 5, 329, 16, 34]	New York University Post-Graduate Medical School, 550 First Ave., New York	B & C	B	1100	Clinical case work Small group discussion	7/ 1/56	C; 12 mo.	815
20 G 753	Internal Medicine [360, 329, 5, 143, 16]	Graduate School of Medicine, University of Pennsylvania, Philadelphia	B & C	B	1280	Laboratory work Clinical case work	9/26/55	C; 8 mo.	1000
21. MALIGNANT DISEASE									
21 G 001	Newer Developments in Cancer Diagnosis and Treatment [5, 226]	City of Hope Medical Center, Duarte, Calif.	C	B	35	Small group discussion Lectures and panels	10/24/55	C; 1 wk.	75
23. NEUROLOGY									
23 G 527	645-A Neurology (Graduate Course) [143, 5, 329, 16]	New York University Post-Graduate Medical School, 550 First Ave., New York	B & C	B	1820	Laboratory work Clinical case work	9/12/55	C; 9 mo.	800
23 G 062	645-A Neurology (Graduate Course) [143, 5, 329, 16]	New York University Post-Graduate Medical School, 550 First Ave., New York	B & C	B	1820	Laboratory work Clinical case work	7/ 1/56	C; 9 mo.	800
23 G 456	Neurology PM 62—Review of Neurology [372]	Montefiore Hospital, East Gun Hill Road, New York 67	B & C	B	72	Clinical case work Small group discussion	9/14/55	I; 3 hr. twice weekly for 13 wk. Tuesdays and Wednesdays	150
23 G 739	Neurology-Psychiatry [368, 329, 5, 113, 16]	Graduate School of Medicine, University of Pennsylvania, Philadelphia	B & C	B	1280	Laboratory work Clinical case work	9/26/55	C; 8 mo.	1000
26. OBSTETRICS									
26 G 939	Postgraduate Anatomy, Obstetrics and Gynecology [414, 415]	University of Alabama Medical Center, 1919 Seventh Ave., South, Birmingham 3, Ala.	B	S	128	Laboratory work Small group discussion	9/20/55	Specially arranged for 36 wk.	Unknown
26 G 474	Basic Science in Obstetrics and Gynecology [143, 423, 349, 16]	New York Medical College, Flower and Fifth Avenue Hospitals, 1 E. 105th St., New York 29	B & C	B	8 mo.	Clinical case work Small group discussion	10/10/55	C; 8 mo.	710
26 G 752	Gynecology-Obstetrics [370, 16, 329, 5, 143]	Graduate School of Medicine, University of Pennsylvania, Philadelphia	B & C	B	1280	Laboratory work Clinical case work	9/26/55	C; 8 mo.	1000
26 G 912	Post-Graduate Course in Obstetrics and Gynecology [5, 436, 169]	Royal Victoria, Montreal Maternity Hospital, 687 Pine Ave., West, Montreal 2, Canada	B & C	S	180	Small group discussion Lectures and panels	8/15/56	I; 5 hr. daily, 6 days wk. for 6 wk.	225
26 G 904	Advanced Graduate Course in Obstetrics [349, 34]	Faculty of Medicine, University of Toronto, Toronto, Canada	B & C	B	240	Small group discussion Lecture and panel	8/22/56	C; 6 wk.	200

27. OPHTHALMOLOGY

27 G 184	Postgraduate Course in Ophthalmology [143, 5, 320, 10, 127]	Illinois Eye and Ear Infirmary of the University of Illinois College of Medicine 901 W. Adams St., Chicago 7	B & O	B	720	Laboratory work Clinical case work	7/ 5/56	C; 6 mo.	500
27 G 199	Basic Science in Ophthalmology [143, 5, 340, 10, 59]	Tulane University School of Medicine 1430 Tulane Ave., New Orleans	B & O	B	1950	Laboratory work Clinical case work	7/ 9/56	C; 12 mo.	500
27 G 260	Lancaster Courses in Basic Ophthalmology [350, 124, 143, 5, 16]	Colby College Waterville, Maine	B	B	425	Laboratory work Small group discussion	6/25/55	C; 11 wk.	325
27 G 220	Anatomy of Head and Neck as They Apply to Eye, Ear, Nose, Throat [5, 21, 143]	University of Maryland School of Medicine 29 S. Greene St., Baltimore 1	B	B	150	Laboratory work Small group discussion	9/15/55	Specially arranged	160
27 G 233	Ophthalmology [310, 143, 5, 331, 140, 16, 380]	Harvard Medical School Courses for Graduates 25 Shattuck St., Boston Massachusetts Eye and Ear Infirmary 243 Charles St., Boston	B & O	B	759	Laboratory work Clinical case work	9/26/55	C; 5 mo.	700
27 G 340	Ophthalmology [143, 5, 320, 128]	Washington University School of Medicine 660 S. Kingshighway, St. Louis 10	B & O	B	1200	Laboratory work Clinical case work	9/19/55	C; 8 mo.	800
27 G 522	576-A Ophthalmology (Graduate Course) [287, 10, 320, 5, 143]	New York University Post-Graduate Medical School 550 First Ave., New York	B & O	B	1125	Laboratory work Clinical case work	9/26/55	C; 9 mo.	815
27 G 917	Combined Eye, Ear, Nose and Throat Course [320, 143]	New York Polyclinic Medical School and Hospital 345 W. 50th St., New York 19	B & O	B	2160	Laboratory work Clinical case work	10/ 3/55	C; full time for 9 mo.	1000
27 G 918	Combined Eye, Ear, Nose and Throat Course [320, 143]	New York Polyclinic Medical School and Hospital 345 W. 50th St., New York 19	B & O	B	2160	Laboratory work Clinical case work	4/ 2/56	C; full time for 9 mo.	2160
27 G 740	Ophthalmology [307, 10, 320, 5, 143]	Graduate School of Medicine, University of Pennsylvania Philadelphia	B & O	B	1280	Laboratory work Clinical case work	9/26/55	C; 8 mo.	1000
27 G 934	Home Study Course in Ophthalmology [438]	Home study by correspondence	B	S	Varies	Assigned reading	9/ 1/55	Specially arranged	20

28. ORTHOPEDICS

28 G 938	Postgraduate Anatomy (Anatomy of the Back and Extremities) [143, 415, 414]	University of Alabama Medical Center 1919 Seventh Ave., South, Birmingham 3, Ala.	B	S	160	Laboratory work Small group discussion	9/20/55	Specially arranged	Unknown
28 G 079	Orthopedic Pathology [143, 5, 340, 10, 102, 431]	Combined course given at School of Medicine, Childrens Hospital, Denver General Hospital 4200 E. Ninth Ave., Denver 20	B	S	90	Laboratory work Small group discussion	9/55	C; 18 wk.	119
28 G 148	Orthopedic Basic Science [143, 5, 10, 64]	Northwestern University Medical School 303 E. Chicago Ave., Chicago 11	B	S	960	Laboratory work Small group discussion	7/ 1/56	C; 6 mo.	600
28 G 201	Basic Science in Orthopedics [143, 5, 340, 10, 100]	Tulane University School of Medicine 1430 Tulane Ave., New Orleans	B	B	850	Laboratory work Operative surgery	2/ 6/56	C; 5 mo.	300
28 G 200	Basic Science in Orthopedics [143, 5, 340, 10, 100]	Tulane University School of Medicine 1430 Tulane Ave., New Orleans	B	B	850	Laboratory work Operative surgery	9/ 7/55	C; 5 mo.	300
28 G 523	581-A Basic Sciences as Related to Orthopedic Surgery [120, 10, 320, 143]	New York University Post-Graduate Medical School 550 First Ave., New York	B & O	S	800	Laboratory work Clinical case work	1/ 3/56	C; 6 mo.	615
28 G 741	Orthopedic Surgery [300, 10, 320, 5, 143]	Graduate School of Medicine, University of Pennsylvania Philadelphia	B & O	B	1280	Laboratory work Clinical case work	9/26/55	C; 8 mo.	1000

29. OTOLARYNGOLOGY

29 G 911	Postgraduate Anatomy (Anatomy of Head and Neck) [143, 414, 415]	University of Alabama Medical Center 1919 Seventh Ave., South, Birmingham 3, Ala.	B	S	160	Laboratory work Small group discussion	9/20/55	Specially arranged	Unknown
29 G 102	Basic Science of Otolaryngology [143, 5, 320, 127]	University of Illinois College of Medicine 1853 W. Polk St., Chicago 12	B	B	1584	Laboratory work Clinical case work	10/ 3/55	C; 9 mo.	750
29 G 167	Clinical and Anatomical Course in Otolaryngology [416, 425]	Indiana University School of Medicine 1100 W. Michigan St., Indianapolis	B	S	150	Laboratory work Lecture and panels	3/19/56	C; 2 wk.	250
29 G 231	Otolaryngology [310, 143, 5, 331, 10, 390]	Harvard Medical School Courses for Graduates 25 Shattuck St., Boston Massachusetts Eye and Ear Infirmary 243 Charles St., Boston	B & O	B	693	Laboratory work Clinical case work	10/31/55	C; 5 mo.	925

Prerequisites

322. 1 yr. internship in general hospital and 2 yr. residency in psychiatry and license.

323. 1 yr. internship in general hospital.

329. M.D. degree from approved medical school and *internship.*

331. Selected by committee on admissions on basis of credentials.

333. 1 yr. formal training or practice.

335. 2 yr. formal training or practice.

337. 2 yr. postgraduate.

339. 3 yr. psychiatric training.

345. 1 yr. psychiatric residence and 1 yr. personal analysis.

346. 2 yr. psychoanalytic training and 1 yr. psychiatric residency.

349. M.D. degree.

351. 2 yr. psychiatric residence plus 3rd yr. before graduation.

354. AS-6: see course 618.

355. A-1, AS-1, A-2 or A-4, A-3, AS-3, AS-6, A-8 or A-9: See 613-616, 618, 620.

357. Acceptance by course director.

360. Graduates in medicine.

375. Doctors with internship and 1 yr. accredited residency in psychiatry.

377. Graduates in medicine; undergraduates who have completed 1 yr. of medical course.

380. Graduate from grade A school, approved internship, under age 40.

396. Degree in arts, science, or medicine, adequate background in physics, chemistry, and biology.

397. Degree in arts, science, or medicine; adequate background in physics, chemistry, and biology, including comparative anatomy or human anatomy and two foreign languages.

401. Basic courses: see 613, 616, 618, 620.

402. Candidate for certificate.

403. Candidate must be in supervision.

404. Decided individually at discretion of American Board in Psychiatry.

405. Matriculated student.

412. Certification as practicing psychoanalyst.

415. Resident of Jefferson-Hillman Hospital.

416. Residency and limited practice.

418. 1 yr. basic science training.

419. 2 yr. graduate training in the specialty.

421. M.P.H. degree.

424. M.D or A.B. or B.S.

432. Qualified psychiatrist.

434. Candidates for American Board of Surgery and F.R.C.S. (C) (Royal College).

435. Exam. American Board of Internal Medicine and F.R.C.P. (C) (Royal College).

436. Candidates for American Board of Obstetrics and Gynecology and F.R.C.S. (C) (Royal College).

439. 1 yr. rotating internship.

441. Graduate of an approved medical school.

443. Rotating internship, 3 yr. postgraduate training.

447. M.D. or other professional training, with experience in field of public health.

449. M.D., M P.H., and departmental invitation.

450. 2 yr. of psychoanalysis.

451. Enrollment in professional school course in institute.

Academic Degree Given

334. Doctor of science in industrial medicine.

336. Master of industrial medicine.

341. Master of public health.

343. Doctor of public health or doctor of philosophy.

374. Psychoanalyst.

388. Diploma of doctor of public health.

391. Bachelor of science (medical).

398. Doctor of science in hygiene.

400. Master of medical science.

420. Doctor of public health.

422. Diploma of doctor of medical radiology.

423. Master of science.

440. Diploma of doctor of industrial hygiene.

442. Master of surgery.

446. Diploma of doctor of psychiatry.

Miscellaneous:

5. Certificate given.

16. Examination given.

37. *Course immediately precedes 4th Western* Cardiology Conference (P-01255). Arrangements for joint registration may be made.

65. Course immediately precedes P-01285, "Electrolyte and Fluid Balance." Arrangements may be made to register for both courses at reduced tuition.

66. One day will be devoted to each of the following areas: internal medicine, pediatrics, surgery, obstetrics and gynecology, psychosomatic medicine and psychiatry, and general medicine. Arrangements may be made to register for single days.

67. Fee for academy members, $10; nonmembers, $20.

74. No fee to members.

99. Course designed for specialists in internal medicine for part 1 and for general practitioners for part 2.

104. Open only to foreign physicians.

105. Monthly.

138. First 3 days, otolaryngology; last 3 days, ophthalmology.

139. $75 for whole course, $40 for either part.

143. Course is accepted for credit by American board in that specialty.

158. All courses given in the evening with the exception of supervision and training analyses. Time for these courses is arranged individually.

166. No charge for residents in radiology or members.

172. No charge for physicians and interns.

179. Associate members, $25.

184. This course, sponsored by the Los Angeles *County Heart Association, consists of a single* 3 hr. laboratory session. Courses are given weekly throughout the year.

189. Alumni, $35.; nonalumni, $100; incoming students free.

213. Fee for members, $35; nonmembers, $50.

241. Nonmembers, $60.

246. $40, association members; $75, nonmembers.

254. The instructor will lecture in each of 5 teaching centers one night a week and repeat the circuit for 10 weeks.

268. Tuition fee: 1st mo., $150; 2nd mo., $75; 3rd mo., $50; 3 following months, $25 each; 1 yr., $450.

273. Additional 6 mo. may be given.

281. Fee paid by North Carolina Health Dept.

284. $5 registration for nonmembers of the American Academy of General Practice.

289. Members only.

298. Tuition for physicians in Oregon is paid by the Oregon Division of the American Cancer Society, and that for physicians in Idaho and Alaska is paid by their local cancer division.

319. Presented by United States Chapter, International College of Surgeons, in cooperation with Cook County Graduate School of Medicine.

324. This course is set up to provide residency training for the physician who is not eligible for a hospital residency because of noncitizenship or other similar reasons.

330. $300 for 6 mo.; $600 for 12 mo.

348. Fee: 1st yr., $500; 2nd yr., $300; 3rd yr., $200.

358. Fee: 6 mo., $500; 12 mo., $1000.

389. Parts of this course may be taken as follows: Basic Sciences in Ophthalmology, 9/26/55-1/20/56; Introduction to Clinical Ophthalmology, 1/23/55-3/3/56.

390. Parts of this course may be taken as follows: Histopathology of the Ear, Nose and Throat, 10/31/55-11/26/55; Anatomy of the Head and Neck, 11/28/55-1/28/56; Audiology, 1/30/56-2/11/56; Anatomy of the Temporal Bone, 2/13/56-3/24/56.

394. $30, members; $60, nonmembers.

399. Affiliated with University of Pittsburgh, Pittsburgh.

409. Fee: $10, residents; $25, practicing physicians.

426. In this course there are 960 hr. plus 3 mo. field work. Less for holders of D.P.H.

427. Residents, $52; nonresidents, $167.

428. Residents, $28; nonresidents, $79.

429. Residents, $28 or $79; nonresidents, $41 or $119.

430. This is a combination course given by the University of Colorado School of Medicine *and Fitzsimons General Hospital.*

431. Residents, $41; nonresidents, $119.

437. Resident, $170; nonresident, $380.

444. Thesis, fellowship in surgery.

452. In this course there are 4 yr. of lectures, seminars, and preceptor sessions (4th yr. courses are elective) as follows: 1st yr., 116 hr.; 2nd yr., 88 hr.; 3rd yr., 103 hr.; 4th yr., 39 hr. The hours of clinical work are in addition to the above.

453. In this course there are 4 yr. of lectures and seminars as follows: 1st yr., 60 hr.; 2nd yr., 60 hr.; 3rd yr., 36 hr.; 4th yr., 66 hr. The hours of field and clinical work are in addition to the above.

MEDICINE AND THE LAW

HOSPITAL STAFF PRIVILEGES CONTINGENT UPON MEMBERSHIP IN COUNTY MEDICAL SOCIETY

The courts have consistently held that the governing body of a public hospital may adopt rules and regulations that are reasonable, that tend to promote efficiency in the running of the hospital, and that are necessary in order that the hospital may better carry out the duties and obligations that it owes to the public.[1] Under this power to prescribe reasonable rules and regulations, it has been held that the governing board of a public hospital may refuse to allow a duly licensed physician and surgeon to practice his profession in the hospital. Such an exclusion must not, however, be based on grounds that are unreasonable, arbitrary, capricious, or discriminatory.[2] The one known exception to this rule occurred in a recent case decided by the Michigan Supreme Court[3] relating to the right of a governmental hospital to determine which physicians might or might not use its facilities. This case was discussed in detail in this column in the April 9, 1955, issue of THE JOURNAL.

In recent years there has been an increasing number of cases before the courts in which the issue was the reasonableness of a particular rule or regulation of the governing body of a public hospital under which a duly licensed physician was excluded from the hospital. Rules excluding osteopathic physicians from public hospitals have been held reasonable on the ground that in the management of a hospital some choice in methods of treatment would seem inevitable.[4] A rule has been held reasonable,[5] which provides that a physician, in order to engage in surgery, must, in addition to being licensed by the state, have had one year of service as an intern in an approved hospital and three years of surgical training that meets the approval of the American College of Surgeons. Also held reasonable was a rule providing that in order to be allowed to perform major surgery in the hospital, the physician had to meet the probationary requirements prescribed by the American College of Surgeons.[6] A rule requiring membership in the county medical society as a condition of being allowed to practice has been held unreasonable.[7] The exclusion of physicians from a public hospital on the sole ground that they were practicing contract medicine has been held to be arbitrary and capricious.[8]

The most recent case with respect to the question of the reasonableness of a particular regulation of the governing board of a public hospital under which a physician was excluded from the hospital was decided by the Supreme Court of Arkansas on June 13, 1955.[9] The plaintiff physician was denied admission to practice in the Ouachita General Hospital, a county hospital supported by public funds. The defendant board of governors of the hospital denied him admission on the ground that he was not a member of the Garland County Medical Society as required by article 5 of the bylaws of the hospital. The plaintiff physician brought his action to enjoin the board of governors from further denying him staff privileges and use of the hospital's facilities. While the action was pending, the board of governors amended article 5 of the bylaws of the hospital so as to make the approval and recommendation of the Garland Medical Society a prerequisite for use of the hospital facilities as a physician instead of the former requirement of membership in the society.

The plaintiff was duly licensed to practice medicine in Arkansas and had practiced in Hot Springs since 1937. During the past 15 years he had made 12 applications for membership in the Garland County Medical Society. Each time his application was rejected without any reason indicated. It was admitted that the plaintiff was excluded from the hospital solely on the grounds that (1) he was not a member of the Garland County Medical Society and that (2) he did not have the approval and recommendation of that society.

The court accepted the general rule that a public hospital may enact rules and regulations applicable to all physicians and surgeons alike that bear a reasonable and fundamental relation to the safety, interest, and welfare of patients and the general public but that its governing authorities cannot exclude a physician by rules and regulations that are arbitrary and capricious. The court, citing in support of its position *Hamilton County Hospital* v. *Andrews*,[10] found that the bylaw in question did not bear a fundamental relation to the safety, interest, and welfare of patients and the general public. The court said that the fact that the board of governors, which was composed entirely of businessmen rather than medical men, needed a group to whom they could turn for advice in considering applicants for staff membership was not sufficient to make the bylaw reasonable. They may consult with and get advice from medical and hospital groups, including county medical societies, in the formulation of rules that bear a reasonable relationship to public safety and welfare, but the rules formulated on the advice of these groups cannot be arbitrary. The rule here in question is arbitrary because the medical society is a private organization whose membership may bestow or withhold approval of a fellow physician's application for a valid reason or for no reason at all. The court stated that as affecting validity, it could perceive "no material difference between a rule that makes membership in a medical society a prerequisite to staff privileges and one that requires approval and recommendation by the membership of said society. An organization that has consistently refused a physician membership over a period of 15 years without any announced reason would hardly be expected to approve and recommend such a physician to staff privileges in the hospital. The membership of a society that would reject the application for membership in the first instance would in all probability withhold its approval in the second instance. It would be contrary to human nature to . . . [suppose] that they would do otherwise."

Counting the subject case there have been only two cases[11] that have passed squarely on the question of whether membership in a county medical society can be made a prerequisite to staff privileges in a public hospital, and both cases have held that such a regulation is arbitrary, capricious, and discriminatory. The point was raised in a third case,[12] but the court deemed it unnecessary to pass on the question since it had declared invalid the rule of the medical society under which the physicians had been denied membership in the society; however, the tenor of the court's opinion is such as to indicate that it would have found the regulation, making society membership a prerequisite to staff privileges in a public hospital, unreasonable. There is also a case[13] involving a private hospital in which it is indicated that membership in a medical society can be made a prerequisite to staff privileges in a private hospital. This is in accord with the established rule that the governing body of a private hospital has an unlimited power with respect to prescribing rules and regulations as to the qualifications and responsibilities of its staff members.[14] Although there have been only these few cases involving the problem, it appears that so long as a county medical society continues to be regarded as a purely private association, with the sole power of determining what persons it will admit to membership, a regulation, such as the one in the present case, will be regarded as arbitrary and unreasonable.

MISCELLANY

THE OUTLOOK FOR SOCIAL SECURITY

A. L. Kirkpatrick

The following article appeared in more detail in the October-November, 1954, issue of American Economic Security. *It is reproduced with the permission of the editor and author.*—Ed.

The great issue of our time—the great basic struggle which underlies most of the apparent disturbances in the world today—is the struggle for the freedom of the individual from domination by others. Men everywhere are striving to assert their God-given right to govern their own lives, make their own decisions, possess property of their own, work at a job of their own choosing, retain the major part of the fruits of their own production and to provide for their own security. Along with the desire for freedom is the almost universal desire for economic security.

It is important to recognize that real security, even economic security, involves a large measure of faith and reliance upon God as the Creator and Governor of His Universe. When individuals, under God's guidance, rely on their own efforts and voluntary private means of providing security, it is attainable, not only without sacrifice of freedom, but actually with greater freedom of thought and action. But the temptation is strong to sacrifice freedom to government or anyone who holds a reasonable promise of a secure income for the future. When the promise offers security for little or no effort on the part of the individual, the temptation becomes very appealing.

FEDERAL SOCIAL SECURITY SYSTEM

Our system of federal social security offers millions of individuals substantial incomes in their later years and that government, or that political party which promises the most liberal benefits for the least cost feels that it has a powerful weapon with which to get and retain itself in power. It is extremely important, therefore, that this system be subjected to periodic review.

The Congress has just enacted extensive amendments to the Social Security Act. It has increased the level of benefits, raised the tax base, added a "freeze" of benefit rights during permanent and total disability and extended coverage to about 10 million additional persons. But at no time since the passage of the law in 1935 has Congress given adequate consideration to any study of what the law should do, what it has accomplished and where it is leading us.

The Senate in 1950 authorized its Finance Committee to make such a study at the same time it increased the benefits and launched the "new start." In fact, the promise to study the system was regarded by some as almost a condition for the passage of the benefit improvement bill. But the study was never made. Nobody seemed to have any stomach for the task. In 1953 the House of Representatives authorized its Ways and Means Committee to make such a study. Congressman Carl Curtis headed the subcommittee which conducted the most thorough-going examination which has yet been made. But its findings and recommendations were almost totally ignored by the House and Mr. Curtis' bill was side-tracked for another which closed its eyes to the present defects of the system. The 1954 Amendments continue the building-up process which has been going on for the last seventeen years without a soul-searching review.

EXPANSION OF THE SYSTEM—1937 TO 1954

Let's look at what has happened since the original law was enacted in 1935. First, benefit levels have been successively increased. The initial current maximum payable to a single beneficiary has risen from $25 in 1935 to $108.50 in 1954. The minimum benefit has been increased from $10 to $30 per month. Benefit payments were to have started in 1942, but in 1939 the date was advanced to 1940.

While the Act at first provided only a retirement income for the worker, plus a cash death benefit to the widow, the 1939 Amendments added a system of dependent and survivor benefits which took the system all the way into the field of life insurance protection. In 1949 the bill passed by the House included permanent and total disability benefits but the Senate bill and the final bill excluded this provision. A disability "freeze" was actually written into the 1952 Amendments but was nullified by another amendment. The recent 1954 Amendments actually puts the "freeze" provision into effect.

The rate of taxation started in 1937 at 1% of payroll for employee and employer and was to have increased by 1% each three years to a maximum of 3%. But Congress acted in 1939 to defer the increase until 1943. Further deferments actually postponed the increase until 1950 when the rate went to 1½%. In 1954, it was increased according to schedule to 2% for employee and employer with the maximum of 4% each now written into the law. The tax base, too, has been increased from its original $3,000 of payroll to $3,600 in 1950 and to $4,200 in the 1954 Amendments. This is a substantial shift in the incidence of the tax to the higher incomes where protection is less needed.

The provision for federal grants-in-aid to the states for old-age relief, which gave the general impression that it was adopted originally as a temporary stop-gap and intended to be sloughed off as the direct payment system took in more and more beneficiaries, has continued in full force and with increasing rather than decreasing amounts. In 1953 federal grants to the states under the Old-Age Assistance program totaled some $900 million. This compares with $119 million in 1937. So we see that the pattern of our social security system during its eighteen years has been one of constant expansion into the area where the federal government takes over more and more of the responsibility for the well-being of its individual citizens.

THE FORCES AT WORK

What are the forces behind this trend? Where will it end? Is it a good thing for the long-range good of the country? The answers to these questions are not easy. We can only judge on the basis of the past record and our present evaluation of them. One of these forces is a strong pressure being exerted through the labor unions and numerous groups organized mainly for the purpose of pressing for federal government largess for, and control over, the lives and well-being of individual citizens. Another factor is a widespread apathy and a lack of understanding of the social security system—its basic philosophy, how it really works, and what its ultimate costs may be. Apathy and ignorance are not forces. Rather, they are vacuums which permit active forces to move in and that is about what has been happening in social security.

Contributing to this indifference is the fact that social security is not an attractive, or even an interesting, subject to the average businessman. He instinctively abhors and shrinks from the idea of a compulsory federal welfare system. He would prefer not to hear about it, let alone study it and work to terminate its evils and put it on a sound basis. He would prefer, if left to his own desires, to close his eyes and ears to what is going on in social security and hope that somehow its evils and abuses would go away. The result has been that the champions of government largess are crusading for a cause where there are few defenders of a sound economy. For the most part, even these few defenders are not well organized, many of them are only partially informed and are without enthusiasm for their cause. Also, it has been quite easy for the welfare advocates to confuse the real nature of the social security system, how it works, its cost and its rapidly accumulating liabilities. This is done by the use of misleading terms. For example, calling it "insurance," speaking of "coverage" and telling its beneficiaries, "you've paid for it, it's yours as a matter of right." How far from the real facts these terms are.

ENCROACHMENT ON PRIVATE LIFE INSURANCE

Still another reason for the relatively easy extension of the program up to date is the fact that many life insurance men apparently became convinced that it was a good thing for private life insurance and stimulated its sale. Agents found it easy to get into an interview by asking the prospect if he would like to know how much his social security pension will be. But the figures don't bear out that conclusion. The assets of the life insurance companies at the end of 1953 were 2.7 times what they were at the end of 1937 when the Social Security Act became effective. The increase is from $29,243,000,000 to $78,533,000,000. Life insurance premiums [almost tripled] in that period, from $3,776,000,000 to $10,847,000,000. Those are very impressive gains. But it must be remembered that, in that period the purchasing power of the dollar has dropped to roughly half its 1937 value, the population and the productive capacity of our people have, on the other hand, increased.

The Gross National Product of the country for 1953 was over 4 times what it was in 1937, increasing from $90 billion to $367 billion, and personal consumption expenditures [more* than tripled,] rising from $67 billion to $230 billion. In other words, the amount of money going into private life insurance has not kept pace with the growth of the country in spite of the impressive gains which its figures show. During that period federal government "life insurance coverage" as represented in the social security system, approached the total life insurance in force in all private companies and went beyond in 1952. With the 1954 Amendments the social security "insurance" coverage exceeds the private volume in about the ratio of 4 to 3. The amount of pensions in force under social security are estimated at roughly ten times the annuity business of the private companies.

PRESENT BENEFITS PAID BY FUTURE GENERATION

Still another reason for the easy expansion of the federal benefit system is because the plan has been so developed that the tax burden falls very lightly on the present generation of workers and voters. We have the unique situation of the present generation legislating one rate of taxation for ourselves today and a progressively higher rate of tax on the next generation to whom we look to pay our old-age benefits.

ULTIMATE END—CRADLE-TO-THE-GRAVE

Where will it end? Are we to see a continuous year-after-year increase in benefit levels, raising of the basis of tax incidence into the higher brackets and the addition of more and more kinds of benefits? I think there is really no question about the ultimate end. The only question is how fast will the rate of progress be made or what can be done to make the Congress face up to the real cost of these benefits. The ultimate goal, advocated by our national labor organizations may be the program embodied in the "Minimum Standards for Social Security" convention adopted at the annual meeting of the International Labor Organization in Geneva in 1952. They are:

1. Old-age and survivor benefits which we already have in this country. The amount of benefits, however, would provide a comfortable living rather than a mere subsistence level to be supplemented by individual efforts;
2. Permanent and total disability benefits;
3. Weekly benefits for unemployment from any cause, whether inability to secure a job, sickness or accident either occupational or non-occupational. This means, of course, the socialization and nationalization of our present workmen's compensation system;
4. Maternity benefits;
5. A monthly payment to each family for each dependent child;
6. A lump-sum job separation payment; and
7. National compulsory health insurance or socialized medicine.

That is the program. In 1952 the labor delegate from the United States and also our government delegate to the ILO voted for it. Our employer delegate alone voted against it. In past years, officials of our social security system and our federal Department of Labor have been active in the ILO movement to get this program adopted, in whole or in part, in all countries of the world.

WHAT WOULD IT COST?

What would such a system of benefits cost? How much of a burden would it put upon our productive machinery? In South America some countries have much of the ILO program already in effect, and their tax rates are as high as 25% of payroll. In France, the tax rate is 35% of much of their payroll and is one of the principal reasons for the failure of the French economy to make a post-war comeback.

Benjamin Kendrick, Research Associate for the Life Insurance Association of America, and a recognized authority in this field, in a public address not long ago, estimated the ultimate cost of the whole program, if put into effect in this country, would be 30% of payroll as a minimum and could cost as much as 40% of taxable payroll.

WHAT'S AHEAD?

What's ahead? What do the advocates of individual responsibility for one's own welfare need to do to put a stop to this unwarranted abuse of the taxing power of government? To put it broadly, it seems obvious that we need to reform our ranks, review both our defensive and offensive strategy and to launch an action program aimed to awaken a sleeping population to what is going on largely unknown to it. At least many people appear to have no conception of the long-range implications and cost of the program that is being gradually projected upon them.

We are living in what Sir Winston Churchill might call an attempted state of "peaceful coexistence" with the welfare pressure groups, with the forces which are seeking to make the individual subservient to government. But Sir Winston also pointed out that any attempt at "peaceful coexistence" with aggressors must be "vigilantly guarded." The businessmen of the country, years ago, accepted our national old-age and survivorship program as a basic part of our economic system, on the premise that it's benefits should be kept at a "minimum level." In the light of the pressures which have developed for more and higher benefits and the relative ineffectiveness of the resistance to this expansion, many are now wondering if they made a mistake in agreeing to "peaceful coexistence."

THE TRAGEDY OF THE OLD FRATERNAL ASSESSMENT INSURANCE PLANS

Some years ago, the fraternal societies of the country were forced to liquidate their early assessment life insurance plans which ended in such tragedy for their longest-lived members and their beneficiaries. The actuaries know the story quite well. Many old time life insurance men remember the cases of policyholders in these assessment plans who paid premiums for many years, only to find that, in their old age, the premiums they had been paying were hopelessly inadequate and that they must now either pay a premium which was virtually prohibitive or expect a greatly reduced payment at the maturity of the policy.

How did this happen? Because the fraternal societies failed to understand the accumulating liability of benefits payable to an aging population. When the lodge members were young men and women, the mortality rate was very low and the cost of insurance was low. But as they grew older, the mortality rate increased and the demands against the funds of the society increased until, finally, they were unable to meet them and were forced to reorganize. The older policyholders lost a large part of their insurance after paying premiums for many years.

Our national old-age and survivorship system is working in much the same way. It was designed to collect taxes from all workers in the covered classes, but to pay benefits in the early years to only a very few. At the beginning of the plan in 1937, taxes were collected from some 32,000,000 persons. But benefits were not commenced until 1940 and, then, were paid only to a part of those taxpayers who had reached age 65. The first year, payments were made to only some 222,000 persons.

FEW ELIGIBLE FOR BENEFITS IN EARLY YEARS

As with the fraternal plans, very few of those covered by social security became eligible for benefits in the early years. But the liability of the system to a slowly aging population continued to creep up year by year. This fact is fully understood by the actuaries but by very few others. The failure to understand this point has accounted, in large measure, for the general public misunderstanding of our system, how it is working and what its real cost is.

With private insurance, every policyholder pays his proportionate share of the total cost of benefits. For a private inurance company to commence paying an annuity of $100 a nonth to a person aged 65, the company must have in hand ome $12,000 to $15,000. That is the "cost" of the benefit.

NOT REALLY "INSURANCE"

With our social security system, the "cost" of benefits is no lifferent than if paid by a private company. The main difference s that our system is depending largely upon its ability to collect axes from the working population of future years. Actually, nstead of our system being an "insurance" system in which ach participant pays the cost of his own benefits, we have a lan in which the working population pays taxes into the fund o be used for the payment of benefits to the non-working aged opulation.

With few, if any, exceptions, every one who is presently reeiving an old-age pension under the social security system has aid for no more than about 5% of the actual cost of his penion. The employer and employee contributions together have iot ordinarily paid for more than 10% of the cost. On the verage, employee taxes have paid for approximately 2% of the ost of their pensions and, together with their employers, they ave paid for approximately 4% of the cost.

The remaining 96% of benefits has been paid, and is being aid, out of the taxes of the present workers. The pensions to hese present workers, in turn, will have to be paid for by the axes of the next generation of workers. While the system has ccumulated a small excess of income over outgo leaving a eserve fund of some $19 billion, the experts indicate that this s not enough to pay the rest of the benefits to those now reeiving old-age pensions and that the accumulated and unisclosed liability for pensions to all those who have paid taxes, mounts to more than $200 billion.

NEED TO PRESENT THE TRUTH

It has been apparent to close students of our federal social ecurity system that some change in the present mechanism is ecessary in order to show plainly to the entire country what he real cost of the existing level of benefits is and then, to have he present generation of the working population pay the full ost of the system in the same way we expect the next generation o pay its cost.

Those who fully understand the system and honestly want to ace the facts don't want to see the country disillusioned some ears hence as were the policyholders and beneficiaries of the ld fraternal societies. Some of the original planners of our resent system now are convinced that, had they known seveneen years ago what they have learned from actual experience ith its operation, they would have insisted upon a somewhat ifferent plan of financing.

On the other hand, there is reason to believe that some of e other planners seized upon the present mechanism for the eliberate purpose of concealing its true cost for many years order to enable them to foist a much greater federal system n the country before the people woke up to its real nature and ost. . . .

WHAT NEEDS TO BE DONE?

In all frankness, it must be admitted that even if nothing is one to resist the trend, even if it is allowed to proceed year fter year unopposed, it may have little adverse affect on most dult citizens. In fact, the further and faster it moves, the bigger enefits elderly individuals will collect when they reach 65. And he effect will scarcely be felt in the tax load which most of em will pay. That is to say, the 1954 Amendments, while inreasing the benefit level, also spread out the tax load and deyed the need for facing up to real costs. It seems likely that ost individuals who are now 45 or over will probably reap e benefits without the deficits from these changes. It will be 0 or 50 years before the system has reached complete maturity nd the real cost laid before the taxpayers of that day.

It does seem somewhat ridiculous and selfish to have the resent generation of employed persons under 65, who constitute e majority of the voters of today, voting larger and larger enefits for themselves, with any one individual and his emloyer so far having paid only 10% or less of the actual cost f the benefits he will get when he retires, and deferring the real ost to the working population of the next generation.

It seems a little incongruous for our Congressmen of today to write into the tax law rate graduate up to 4% each on the employer and employee of 20 years from now in order that they may pay benefits to many of those who paid only 1% each, and for a time 1½% each. I wonder what the attitude of the next generation of taxpayers will be? Will they pay the bill or will they find some scheme for avoiding that burden as we have done?

MEDICAL FILM REVIEWS

Ocular Bacteriology: Its Application to Clinical Practice: 16 mm., color, sound, 40 minutes. Sponsored by Alcon Laboratories, Fort Worth, Texas. Produced in 1954 by and procurable on loan from Medical Film Guild, Ltd., 506 W. 57th St., New York 19.

This film is a clinical symposium on the bacteriology of the eye. It consists of a panel discussion by the following persons: James H. Allen, Tulane University, moderator; Trygve Gundersen, Boston University; Phillips Thygeson, University of California; Hugh Ormsby, University of Toronto; Alson E. Braley, University of Iowa; Michael J. Hogan, University of California; and Gustav C. Bahn, Tulane University. The most important aspect of the film is its plea for recognition of the diminishing effectiveness of antibiotics in the treatment of infections of the eye. It urges the inclusion of bacteriological studies in the routine examination of every patient with inflammatory or infectious disease of the eye. The purpose of this rather long film is to emphasize the importance of specific diagnosis and ocular bacteriology in external ocular diseases. The general technique for taking a culture, plating the material, doing sulfonamide and antibiotic sensitivity tests and a few examples of morphology of conjunctival smears are presented effectively. Several types of external ocular infections are presented as illustrations of occasions when the making of a bacteriological culture and smear would be of diagnostic value. The quality of photography and the presentation are excellent; however, the voices of various members of the panel reproduce very poorly. It is somewhat difficult to decide at what type of audience this film is directed. It would emphasize to the general practitioner the importance of ocular bacteriology in making accurate diagnoses of external ocular inflammations; however, the general treatment of the subject, as to both the comments of the panel and isolated examples of many different types of external ocular infection, was superficial and would be of little interest to the average ophthalmologist. To an ophthalmologist with satisfactory previous training, a more thorough demonstration of fewer conditions with greater details of technique and findings would probably be of greater interest.

Cancer of the Urinary Bladder: Kinescope No. 23. 16 mm., color, sound, showing time 47 minutes. Prepared by Willet F. Whitmore, M.D.; Victor F. Marshall, M.D.; and James L. Green, M.D., Memorial Center for Cancer and Allied Diseases, New York. Produced in 1954 by and procurable on loan from American Cancer Society, 521 W. 57th St., New York 19.

This film was originally produced for closed-circuit television. The significant signs and symptoms and the techniques used in differential diagnosis of cancer of the bladder are described. Therapeutic approaches, including the rationale of radical surgery, are reasoned through. Clinical case histories, descriptions of gross and microscopic pathology, results of varied treatments, preoperative evaluation procedures, techniques of postoperative care, and the rehabilitation of patients after extensive surgery are all defined. There is a discussion of the incidence and location of bladder tumors and a discussion of urographic findings in a patient with carcinoma of the bladder. A very strong plea is made to the general practitioner for the early recognition of the symptoms of bladder tumors. The material is presented in a very clear, concise, factual, and well-organized manner. The dialogue is very good. Charts and diagrams are clear and effectively presented. This film is highly recommended for general practitioners and would also be of value in teaching residents, interns, and medical students.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Cardiac Rupture: Report of 12 Cases from the Southern Baptist Hospital, New Orleans, During a 10 Year Interval. S. H. McDonnieal Pr., M. Humbrecht and N. W. Voorhies. J. Louisiana M. Soc. **107**:171-177 (May) 1955 [New Orleans].

Of 1,315 consecutive autopsies performed at the Southern Baptist Hospital in New Orleans between 1944 and 1953, acute myocardial infarction was found as the cause of death in 114. Cardiac rupture had occurred in 12 of the 114 cases, an incidence of 10.5% of all acute infarcts, in which autopsy was performed. Of the 12 patients between the ages of 54 and 85 years with cardiac rupture, 8 were women and 4 were men. The higher relative incidence of spontaneous cardiac rupture, as compared to that of acute myocardial infarction in women, may be attributed to the lower incidence of coronary disease and the higher incidence of hypertension among women. In none of the patients was the diagnosis of cardiac rupture made before death, although it was suspected at the time of death in two. Cardiac rupture occurred within four days of the onset of the infarct in eight patients (66.7%), on the fifth day in one, and on the 12th and 14th days in one each; no history of the onset of the infarct was available in one patient. The time of rupture in the authors' patients followed the same pattern as that reported by other workers. Since most ruptures occur within the first week and nearly all within the first two weeks, and since the incidence of rupture is increased by unrestrained activity, the physician is justified in insisting on at least three weeks of complete rest. This would apply equally to the so-called small infarct, particularly when the blood pressure remains high after infarction. Only one of the 12 patients received anticoagulant therapy, and only a single dose of ethyl biscoumacetate (Tromexan) three hours before death. Consequently, no conclusions can be drawn from the authors' series concerning the possible effect of anticoagulants on cardiac rupture, but reports by other workers suggest that anticoagulants carry a definite risk in addition to the systemic effects of the drugs. The occurrence of cardiac tamponade, as well as the increased frequency of rupture, limits the usefulness of anticoagulants in the care of the patient with acute myocardial infarction.

The Effects of 1-Hydrazinophthalazine upon Coronary Hemodynamics and Myocardial Oxygen Metabolism in Essential Hypertension. G. G. Rowe, J. H. Huston, G. M. Maxwell and others. J. Clin. Invest. 34:696-699 (May) 1955 [New York].

Six patients with essential hypertension were given 11 to 20 mg. of 1-hydrazinophthalazine (Hydralazine) hydrochloride, and five hypertensive patients serving as controls were given 1 cc. of sodium chloride solution. Various cardiac functions were determined before and after "treatment." In comparison with the results in the controls the hemodynamic changes that occurred after the administration of Hydralazine included an increase in heart rate, a fall in systemic blood pressure and peripheral arterial resistance, a decreased arterial and mixed venous carbon dioxide content, and a smaller arteriovenous carbon dioxide difference. Total body carbon dioxide production and oxygen consumption were unchanged, and the respiratory quotient was constant. Hydralazine produced an increase in coronary blood flow in five of the six patients to whom it was given, the over-all increase being 34%. Simultaneously, with the decrease in perfusion pressure, the coronary vascular resistance was decreased 35%. The increased coronary blood flow was accompanied by a 27% decrease in the arterial-coronary sinus oxygen difference caused by an 81% increase in the coronary sinus oxygen content. The cardiac rate of oxygen consumption remained unchanged. Hydralazine thus decreases coronary vascular resistance to such a degree that an increase in flow occurs despite the reduced prefusion pressure. Simultaneously, as arteriovenous oxygen difference across the myocardium narrows, left ventricular oxygen consumption per 100 gm. is unchanged.

Some Observations on the Epidemiology of Lung Cancer. R. Fowler. M. J. Australia **1**:485-494 (April 2) 1955 [Sydney, Australia].

An isolated inquiry has been made in the last 10 years in order to compile and analyze data regarding patients with cancer at six public hospitals in Melbourne, Australia. A summary of this inquiry discloses that admissions for bronchial cancer have more than trebled in the last decade. Throughout the series the ratio of male to female patients has never been less than 4:1. At the same time the ratio of patients with bronchial cancer to all patients with cancer has increased from 1:38 in 1940 to 1941 to 1:15 in 1952 to 1953. Since the case fatality rate of lung cancer is practically 100%, it can be seen that, except for an indeterminate time lag between the onset of disease and death, the long-term trend of mortality may be used as a measure of the incidence of lung cancer. A synopsis of Australian mortality data for primary growths of the lung reveals a great increase in the number of deaths ascribed to cancer of the lung in the last 40 years. By 1950, physicians in Australia were writing "cancer of the lung" on death certificates about 27 times more often than in 1910. Statistical analysis of the Australian death rates appears to indicate that: (1) the frequency of occurrence of bronchial cancer has undergone a marked increase in the last 40-odd years; (2) the incidence of this disease has increased by a more or less constant percentage each year; and (3) the uniform pattern of increase has been slightly disturbed by irregular deviations from the "normal" upward trend, but there has been no evidence of epidemic cycles. Analysis of the sex-specific time sequences discloses that, although each sequence exhibits an exponential trend like the parent series, the gradient or rate of climb is much steeper for male than for female mortality rates. The increase is about 7.7% per annum in the case of men and 4.6% per annum in the case of women. A detailed analysis of the clinical features of 1,000 case histories illustrates the difficulties of early diagnosis and the limitations of ablative surgery in dealing with the disease. The evidence from Britain and the United States of America, which incriminates smoking as a lung cancer pathogen, is regarded as convincing. The smoking habits of Australians are thought to be consistent with the theory that habitual heavy smoking is similarly blameworthy in Australia. Miners of nickel, cobalt, and uranium ores appear to be subject to special hazards. This is of interest to Australia because uranium fields are about to be exploited.

Severe Upper Gastrointestinal Hemorrhage: Early Use of Diagnostic Technics. E. D. Palmer and N. M. Scott Jr. Connecticut M. J. **19**:368-372 (May) 1955 [New Haven, Conn.].

A vigorous diagnostic approach was adopted by the authors in 163 patients with severe upper gastrointestinal hemorrhage. As soon as the patient was admitted to the emergency room, blood was drawn for cross matching, and blood replacement begun and continued as the clinical course dictated. Ice-water lavage was carried out for a half hour with a large-caliber tube using several quarts of ice-water, and esophagoscopic examination was made as soon as the tube was withdrawn. The esopha-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

oscope was passed under direct vision rather than with the elp of an obturator because of the importance of inspecting he hypopharynx on the way down. Gastroscopic examination mmediately followed esophagoscopy, unless the latter showed he stomach to be refilling with blood, whereupon lavage was epeated first. Fluoroscopic examination immediately followed astroscopy, even though the bleeding lesion had already been ound. The details of diagnostic management varied to some extent from patient to patient, but in the 53 most recent cases ll diagnostic studies were completed within 24 hours of hospitalization. The examinations that were performed during emorrhage included esophagoscopy in 105 patients, gasroscopy in 136, and contrast fluoroscopy in 159. The initial mergency diagnostic studies permitted identification of the leeding lesion in 136 (83%) of the patients. As a result of successful early diagnostic efforts, 29 patients were given emerency surgical treatment during or shortly after the acute leeding episode. Of these 29 patients, 10 had duodenal ulcer, gastric ulcer, 9 esophageal varices, and 2 hiatus hernia. In rder to examine the effectiveness of this vigorous diagnostic pproach, the 163 patients were compared with 212 control atients in whom no search was made for the bleeding site until t least seven days had passed since cessation of hemorrhage, xcept that permitted during emergency laparotomy in 25 paients. The initial working diagnosis proved to be correct in only 4 (35%) of the 212 patients. Emergency therapy proved optimum in 86% of the patients with vigorous diagnostic approach s compared to 55% of the patients with delayed diagnostic pproach. The source of hemorrhage was not determined in 1% of those with vigorous diagnostic approach as compared o 15% in those with delayed diagnostic approach. There were deaths from hemorrhage among the 163 patients, a mortality ate of 4%, as compared to 18 deaths from hemorrhage among he 212 patients, a mortality rate of 8%. Nothing was observed o suggest that the vigorous diagnostic approach aggravated emorrhage or in any way compromised the patient's chance f survival. Early establishment of a precise diagnosis is important in clinical management whatever form treatment may ake, but its value is most dramatically shown when an emergency operation is required. Little weight can be placed on a history of previous diagnosis in guessing at the cause of a current hemorrhage. This mainstay of the conservative diagnostic approach proved wholly unreliable in the authors' study. Direct, on-thespot visualization of the lesion responsible for the severe upper gastrointestinal hemorrhage made it possible to direct treatment specifically. A significant reduction in mortality was achieved.

Clinical and Pathologic Difference Between Regional Enteritis and Ulcerative Colitis. E. J. Lowell Jr. J. Internat. Coll. Surgeons 23:513-516 (April) 1955 [Chicago].

Judged on the basis of general hospital admission, ulcerative colitis is from 30 to 40 times as common as is regional enteritis, and is more often encountered in women than in men. In contrast, 56% of regional enteritis occurs in men. Regional enteritis is an inflammatory disease of the small intestine characterized by abdominal cramps, diarrhea, fever, anemia, loss of weight, and anorectal complications. Ulcerative colitis is also an inflammatory disease, occurring for the most part in the large intestine characterized by bloody diarrhea, abdominal cramps, loss of weight, and anorectal complications. Enteric and abdominal fistulas are more common in patients with regional enteritis, while anorectal infections are more commonly associated with ulcerative colitis. Three prominent signs in patients with regional enteritis are a tender, fixed mass in the lower part of the abdomen; irregular fever; and negative results from sigmoidoscopic examination. Two prominent signs associated with ulcerative colitis are abdominal tenderness over the colon and positive results from sigmoidoscopic study. When present, diagnostic roentgenographic signs of regional enteritis consist of the "string sign," a distorted, narrowed, irregular lumen with loss of the mucosal pattern. In patients with ulcerative colitis, the diagnostic roentgenographic signs, when present, consist of the "lead pipe" colon, a shortened, smooth, rigid colon with loss of haustral markings. Carcinoma of the colon develops in up to 14% of patients with ulcerative colitis, whereas it virtually never occurs in those with regional enteritis. The pathological aspects of the two diseases differ even more decidedly than do the clinical aspects. The small intestine in a patient with regional enteritis is reddish-purple to grey, thickened, and suggestive of a rubber hose. The mesentery is stiff and edematous. White granular nodules may be visible, and enlarged lymph nodes palpable, in the mesentery. The opened specimen of small intestine appears cobbled, congested, and dusky red. On closer inspection longitudinal ulcerations are seen. In contrast, the colon in ulcerative colitis may show little external abnormality. Redness or spasticity may be the only external manifestation at operation. The mesentery may be normal, with few enlarged lymph nodes, unless the disease is advanced or complicated by carcinomatous change. The most striking change will be noted on examining the colonic mucosa. The entire lining often appears diffusely congested, ulcerated, and inflamed. With respect to microscopic pathological changes, the chief change attributable to regional enteritis is progressive sclerosing granulomatous lymphangitis affecting all layers of the small intestine, the lymph nodes, and the mesentery. In contrast, ulcerative colitis is restricted mainly to the colonic mucosa and submucosa.

SURGERY

Excision of an Aortic Aneurysm Adjacent to the Celiac and Superior Mesenteric Arteries: Report of a Successful Case. H. D. Sirak. Ohio M. J. 51:344-346 (April) 1955 [Columbus, Ohio].

Sirak reports the case of a man, aged 43, with a diagnosis of aortic aneurysm. The patients had been suffering from epigastric pain for eight years. At the age of 15 he had had a penile chancre, which he had treated with a salve. He had not received any other antisyphilitic treatment. Operation was performed under endotracheal ether-oxygen. Because the aneurysm was located in the lower part of the thorax and extended beneath the left diaphragm, the incision was placed in the left seventh interspace starting at the posterior axillary line and carried down onto the abdomen as a left paramedian. The aneurysm was approximately 12 cm. in diameter. It was joined to the left lateral wall of the aorta at the same level as the origins of the superior mesenteric and celiac arteries by a neck 5 cm. wide. The neck extended to a point that was 1 cm. above the left renal artery. The aorta in the immediate area of these vessels was not involved. The course of the operation, in which the syphilitic aortic aneurysm situated at the level of the celiac axis and superior mesenteric artery was successfully excised and lateral aortorrhaphy performed, is described. The patient withstood total occlusion of the aorta at the level of the ninth thoracic vertebra for 41 minutes without ill effect. This attests to the adequacy of the collateral circulation for the maintenance of the liver and the other viscera for this period of time. The results obtained establish surgical excision as feasible and practical in the extirpation of this otherwise fatal lesion. The author feels that if any attempt had been made to free-up and clamp the neck of the aneurysm in order to avoid cross clamping the aorta, the aneurysm would have been torn, resulting in massive hemorrhage. The evidence for this statement was amply demonstrated as the aneurysmal sac was being detached from the parietes after repair of the aorta had been successfully concluded. Whereas the anterior wall appeared substantial, the posterior wall of the neck and sac was tissue-paper thin and was very adherent to the posterior chest wall. This is explained by the fact that aneurysms in this area are "blowouts" with walls composed primarily of adventitia that readily gives way laterally beneath the parietal pleura. The parietes, because of this intimate relationship, become a part of the aneurysm's posterior wall. In contradistinction, aneurysms of the ascending aorta and aortic arch area do not have this relationship and are amenable to clamping at their necks.

Bilateral Adrenalectomy and Oophorectomy in the Treatment of Recurrent Carcinoma of the Breast. J. P. Eddy. Rhode Island M. J. 38:207-209 (April) 1955 [Providence, R. I.].

Total adrenalectomy, with or without concomitant oophorectomy was performed by Eddy on eight patients with advanced breast cancer. Seven were operated upon prior to January, 1954, and have a sufficiently long follow-up to make the analysis significant. All of these patients were selected for treatment on the basis of widespread metastatic disease, some had previously undergone x-ray therapy and hormonal therapy, or both. The operation required about two hours. The adrenals were removed with the patient in the posterolateral position, after resection of the 12th rib. The ovaries were removed by turning the patient from one side to the other when necessary. The severely ill patients withstand the procedure remarkably well. There was no operative death. Two of the seven patients are now dead and showed no significant response to the treatment. Four have improved markedly and are leading essentially normal lives. One has improved moderately, leading a somewhat restricted but still painless existence. The average patient who can withstand a major surgical procedure can also withstand bilateral oophorectomy and adrenalectomy. In addition to the usual preoperative preparation for major surgery, such a patient is given 50 mg. of cortisone intramuscularly every six hours, the day before operation, including 5 mg. of desoxycorticosterone acetate intramuscularly, and 5 gm. of salt is added to the diet. The morning of the operation another 50 mg. of cortisone and 5 mg. of desoxycorticosterone acetate are administered. During the operative procedure 1,000 cc. of blood is given, and if necessary, the blood pressure is supported by injection of norepinephrine. The first 24 hours postoperatively the patient receives 50 mg. of cortisone intramuscularly every six hours, and one injection of 5 mg. of desoxycorticosterone acetate. During the second 24 hours after operation 50 mg. of cortisone is given intramuscularly every 8 hours with 5 mg. of desoxycorticosterone acetate. On the third postoperative day 50 mg. of cortisone is given every 12 hours with 3 mg. of desoxycorticosterone. On the fourth day cortisone may be given by mouth, 25 mg. every six hours, and thereafter 3 mg. of desoxycorticosterone acetate every other day. Cortisone therapy is reduced to a basal dose of 25 mg. twice a day. Salt is added to the diet (approximately 3 gm. daily). These patients are instructed to consult a physician in case of any sudden unexpected stress that may change their metabolic requirements. Malaise, weakness, orthostatic hypotension, sweating, and tachycardia may all suggest impending adrenal crisis and should be promptly recognized and treated.

Plasma Cell Mastitis: A Review and Report of a Case. B. E. Ferrara. Am. Surgeon **21**:376-384 (April) 1955 [Atlanta, Ga.].

Plasma cell mastitis is a rare condition of the female breast which simulates mammary cancer. Ferrara reports a case of a woman, aged 27, who complained of a swollen right breast. She had been delivered of a normal child three weeks before. She did not nurse the baby. Several days following the birth of her child, soreness and redness of the skin of the breast was noted. She was seen by another physician who treated her with local applications and daily penicillin injections for several days. The inflammation partially subsided, but there remained a firm movable mass, 3.5 cm. in diameter, in the lower medial quadrant of the right breast, with minimal local heat and redness of the overlying skin. The mass was not painful, but seemed to be adherent to the chest wall. No axillary nor supraclavicular nodes were palpable. The mass was excised. The diagnosis of plasma cell mastitis was made after study of the specimen. Adair called attention to this condition with his publication of 10 cases in 1933. A total of 76 reported cases are tabulated. Two phases of the disease have been described by Adair. 1. The acute phase is characterized by signs of inflammation in the breast that subsides after several weeks to a month. The symptoms may vary in intensity; inflammation may be so mild as to be forgotten by the patient. There may be chills and fever. The breast may be tender, swollen, and reddened. A creamy nipple discharge is frequent. Usually more than one quadrant of the breast is involved. The axillary nodes are usually enlarged. As the inflammatory reaction subsides, the breast becomes less red in color, less swollen, somewhat nodular, and with better localization of the process. This latter occurrence has been referred to as the subacute phase. 2. In the residual phase all signs of inflammation have subsided. A discrete, firm, well-defined, deep-seated mass is present in the breast. Skin fixation may be present, and fixation to the chest wall may occur. The mass may be painful. Nipple discharge, which usually is creamy and thick (and may be bloody), is common. Nipple retraction is frequent. The axillary nodes frequently are palpable. The clinical picture is that of carcinoma. The residual mass may be present for several years before excision, or it may completely disappear without treatment. It is a disease of parous nonlactating women. There is general argeement that the lesion is inflammatory. Most observers believe that the cause is chemical rather than bacterial. Adair described the pathological characteristics: (1) the presence of plasma cells in the breast occurring in broad sheets and infiltrating ducts, duct walls, and interstitial tissues; (2) the proliferation of duct epithelium piling up 6 to 10 rows deep; and (3) the formation of giant cells by the heaped-up lining cells. The histological appearance may resemble comedocarcinoma due to the proliferation of duct epithelium. It also resembles tuberculosis, but there is no caseation.

Bronchial Carcinoma: Survey of 317 Patients. J. R. Bignall. Lancet **1**:786-789 (April 16) 1955 [London, England].

One of the two hospitals in which these studies were made specializes in diseases of the chest and the other in cancer. Many patients are first seen elsewhere and are sent to these hospitals for bronchoscopy, surgical treatment, radiotherapy, or a second opinion. During 1951, 317 patients with bronchial carcinoma attended the hospitals. The diagnosis was based on histological evidence in 199 (62%) patients. One-fifth of the patients had had symptoms or signs for less than two months, but half had had them for more than four months, and a tenth for more than a year. Almost a third had clinical or radiographic evidence of metastases when first examined. Even when symptoms had been present for less than a month, 1 in 20 had metastases; and the proportion rose to a half in those with symptoms of five months' duration. Thoracotomy was precluded in 40% because of intrathoracic or extrathoracic spread; and in a third because of the position of the growth, deficient respiratory function, gross wasting, refusal to be investigated, or incorrect diagnosis. The chest was explored in a quarter, but in about a third of these the tumor could not be removed. Resection was possible in only 18% of the 317 patients. A little over a third received radiotherapy. A third survived a year from the first attendance and a sixth two years. A quarter were alive two years after the start of their illness; 31 of these 77 patients had had the tumor removed. The manner of dying was recorded in 128 patients. Of 25 who died after resection, 10 had clinically manifest cerebral metastases, compared with 16 of 103 who had not had the tumor removed. Bignall believes that the course of the disease in these selected patients, unfavorable as it is, is better in some respects than that of patients with lung cancers generally. Many old people may never reach chest clinics or special hospitals; and some die with metastases in the brain or elsewhere before the existence of the primary tumor is known. In 18% of the present group it was possible to remove the cancer. If the tumor is not removed few patients live longer than two years from the first manifestation of the disease. By the time a bronchial carcinoma causes symptoms obtrusive enough for the patient to seek advice the tumor has often spread beyond the lung. Even with the most efficient medical service and a population conditioned by propaganda to a delicate balance between hypochondriasis and ignorance, it seems unlikely that the proportion of those with eradicable tumors could be greatly increased. Even detection by mass radiography is unlikely to increase it dramatically.

Kartagener's Syndrome: Surgical Treatment: Lobectomy and Segmentectomy. J. A. Taiana, A. J. Villegas and E. Schieppati. Rev. Asoc. méd. argent. 48:565-568 (Dec. 15-30) 1954 (In Spanish) [Buenos Aires, Argentina].

Kartagener's triad of congenital malformations of all the viscera and the structures of the respiratory tract is rare. It consists of situs inversus totalis, bronchiectasis, and rhinopharyngosinusopathy. The case reported by the authors is the ninth in the Argentinean literature. The patient had had poor general health, chronic bronchorrhea, and other respiratory symptoms since birth. At the age of 21, the predominant symptoms were fatigability and acute mucopurulent bronchorrhea with a daily sputum volume of 200 cc. Clinical, electrocardiographic and roentgenographic examinations, and bronchoscopy showed situs inversus totalis and large cylindrical and saccular bronchiectasis in the lower lobe of the left lung, which was located in the right hemithorax, and in the lingula pulmonis and the anterior segment of the upper lobe of the same lung. An operation was planned. Preoperative treatment, consisting of a hygienic diet, antibiotics, aerosols, vitamins, liver and iron therapy, postural and gymnastic exercises, and treatment of the rhinopharyngeal disease by a specialist was given for seven months, at the end of which time the patient's general health was greatly improved, and he had gained 17 kg. (37.5 lb.). In this period his sputum volume dropped to 50 cc. a day. A right thoracotomy, removal of the lower lobe of the left lung, lingulectomy, and removal of the anterior segment of the upper lobe of the left lung were performed. The postoperative course was uneventful. The patient continued to gain weight, his general health improved, and the bronchorrhea was almost completely controlled. An excellent readjustment of the thorax with complete pulmonary reexpansion was observed in the roentgenograms.

NEUROLOGY & PSYCHIATRY

After-Examination Following Poliomyelitis Epidemic in Buskerud in 1951. L. Stang. Tidsskr. norske lægefor. 75:265-267 (April 15) 1955 (In Norwegian) [Oslo, Norway].

On follow-up examination of 224 patients treated during the 1951 poliomyelitis epidemic 116, or 51.8%, were able to work. If patients able to do light work are included, the figure is 162, or 72.3%. Thirty-eight patients, or 17%, were found to be severely disabled, and 24, or 10.7%, were dead. Forty-five, or about 28%, of the paralyzed group were still under treatment. It was concluded that those with the bulbar and encephalitic types have a relatively good prognosis if they can be brought through the acute phase of the disease. Here active therapy with early tracheotomy and oxygen has its greatest value. Of the 12 patients in this group, seven escaped noteworthy disability and 5 died. Paralyses occurred in 72.3% of the patients, spinal paralysis dominating. Twenty orthopedic operations were performed on 17 patients.

Course of Myasthenia After Denervation of the Carotid Sinus. H. G. Mertens. Nervenarzt 26:150-154 (April 20) 1955 (In German) [Berlin, Germany].

The first of the four patients with myasthenia presented by Mertens was a 46-year-old woman, in whom muscular weakness had been increasing gradually for 16 years, so that she had ptosis, could walk only a few steps, and could not dress herself. Bilateral exclusion of the glomus caroticus was carried out by infiltration with procaine hydrochloride. A noticeable increase in muscular power resulted, which persisted for several hours. After several repetitions of this test, surgical denervation of carotid sinus was performed on one side. This was followed by marked improvement, which lasted for only about eight days, except for improvement in chewing, which persisted longer. Three weeks after the first operation denervation of the carotid sinus was performed on the other side. This again was followed by great improvement in muscular power, which persisted for only 8 to 14 days. At the end of eight weeks the condition was worse than before the operation and the patient was practically helpless, even if she took 10 tablets of prostigmine. After that there was gradual improvement, over a period of about six months, so that the patient was again able to do her housework and even dance. This improvement had persisted for one year when the patient was last seen. Similarly favorable results were obtained in a 47-year-old man, in whom signs of myasthenia had been present for 10 years, and who recently had become bed-fast. Definite improvement was evident after the first and second operation, and this improvement gradually progressed over a period of six months, the patient being able to take long walks and requiring only one to three tablets daily. Nine months after the operation progressive exacerbation set in again, so that the patient's condition was hardly any better than before the operation. Denervation of the carotid sinus was performed also in two young women, in whom signs of myasthenia had been present for only one and three years, respectively, but improvement lasted only a few days. The author was unable to obtain results as favorable as those of other investigators, who resorted to this method on the basis of animal experiments.

Treatment of Temporal-Lobe Epilepsy by Temporal Lobectomy: A Survey of Findings and Results. M. A. Falconer, D. Hill, A. Meyer and others. Lancet 1:827-835 (April 23) 1955 [London, England].

Epilepsy of temporal lobe origin may not be controlled by anticonvulsant drugs. Sometimes it is caused by a tumor, angioma, or cyst, and it may cease when this is excised. More often, however, the underlying lesion is microscopic in size and hard to detect. The clinical pattern of the seizures and their association with epileptic electroencephalographic discharges in one or both temporal lobes may be the only guides. In the three years preceding March, 1954, the authors treated 31 patients, with intractable epilepsy of this type, by resection of the responsible temporal lobe. Since one of the 31 patients died shortly after the operation, 30 cases are reviewed. Twenty-three came from the epileptic practice of a psychiatric hospital and the remainder from a general hospital. Hence it is not surprising that all but one of them also had a definite personality disorder. The sexes were equally represented. The ages, at the time of operation, varied from 2½ to 56 years. Each patient exhibited a variety of attacks. Amnesic seizures without a major convulsion but associated with auras of an epigastric, olfactory, gustatory, cephalic, or psychical character (psychomotor attacks) occurred in all. Many patients had also noticed that these auras sometimes appeared without any dazedness or amnesia. Grand mal seizures had occurred in 12 patients several times, in 9 they could be excluded, and in the remaining 9 they had either been very occasional or else the history was not sufficiently comprehensive to exclude them. The associated personality disturbances varied greatly. A characteristic feature was a history of emotional disorder and of poor adaptation to social demands, work, and sexual life of long duration. Most patients had been under medical supervision for many years, and their attacks had continued in spite of long and adequate trials of various anticonvulsants. Before operation, all patients, besides having a comprehensive psychiatric assessment, were subjected to detailed neurological, electroencephalographic, and neuroradiological examinations. Twelve of the 30 patients were freed from their epileptic attacks, and in 14 others the epilepsy was greatly improved. Twenty were benefited as regards their personality changes. The authors believe that the high frequency with which pathological changes have been found in the resected temporal lobes and the high rate with which relief or improvement has followed operation suggest that the lesions observed and the symptoms relieved were related.

Histamine Therapy for Schizophrenia: A Follow-Up Study. A. Hoffer and S. Parsons. Canad. M. A. J. 72:352-355 (March 1) 1955 [Toronto, Canada].

Histamine therapy, in the form recommended by Sackler and others, was used in 12 schizophrenic patients in a psychiatric ward of the Regina, Sask., General Hospital. Nine of the 12 patients were improved on discharge, but although only 4 retained their improvement at follow-up, all 12 were living in the community, and if the only criteria of improvement were discharge from hospital, a perfect treatment response might be claimed. Four patients attained a satisfactory adjustment in interpersonal relationships, social activities, and vocation, and they are better than they were before their illness. These four were less than 25 years old, but of the eight who did not improve only two were under age 25.

GYNECOLOGY & OBSTETRICS

Treatment of 850 Cases of Simple Uterine Hemorrhage by Intra-Uterine Application of Radium. W. Barr and A. A. Charteris. J. Obst. & Gynaec. Brit. Emp. *62:187-194 (April)* 1955 [London, England].

Excessive functional uterine bleeding, especially when it occurs about the time of the menopause, was formerly often treated by inducing an artificial menopause with the aid of radium. The results obtained were satisfactory as regards control of the hemorrhage, but some criticized the method on the grounds that it produces unusually severe menopausal symptoms, local tissue necrosis, and even an abnormal incidence of uterine neoplasms. The results obtained at the Western Infirmary of Glasgow during the years 1926 to 1949, when 850 patients were treated by intrauterine application of radium, were analyzed. The primary treatment produced satisfactory results in 774 patients, while 56 required further treatment. Menstruation was reestablished in 10 women, each of whom belonged to a younger age group than would now be treated, and 22 patients were lost from the follow-up. There were no deaths and few postoperative complications. There was no evidence that the menopausal symptoms were unusually severe or greatly different from what might be expected in the natural menopause. The age of the patient seems to play a part, in that a higher incidence of severe symptoms occurred in patients under 42 years of age. This suggested that 42 is the lowest age at which the artificial menopause should be induced. Four patients developed some form of neoplasm at a later date, but only two involved the uterus; one was a cervical carcinoma, which the authors do not regard as a sequel of the radium treatment. This leaves only one patient in the series who had adenocarcinoma of body of uterus and this seems a very low incidence in 850 cases. Lately a second patient was found in whom carcinoma of the body of the uterus developed. The authors do not regard this alleged hazard as a contraindication to radium treatment.

The Natural History of Pelvic Tuberculosis. T. Barns. J. Obst. & Gynaec. Brit. Emp. *62:162-175 (April) 1955* [London, England].

To ascertain the mode of invasion of the genital tract, studies were made on 107 women with genital tuberculosis attending the gynecologic department at the Newcastle General Hospital in the past 11 years. Laparotomy had been performed in 55 in this department, providing an opportunity to obtain information concerning the presence of abdominal tuberculosis. In a further 25 patients a laparotomy had been performed before coming under observation. Curettage was performed in 83 patients. Histological examination, biological examination, and direct culture were carried out in all cases, and a culture was also obtained from the spleen of the inoculated guinea pig in 27 cases. Eighty-seven patients were radiologically examined; in many of the patients former chest films were obtained from other hospitals. The most significant information, however, was obtained through a careful history. Seventy-three per cent of the patients had evidence of other forms of tuberculosis; pleural effusion and tuberculous peritonitis each occurring in about 33% of the patients. In only eight patients were these coexisting lesions still in an active state. The primary site of tuberculous infection was located in 57 patients; this was found to have been in the lung in 46; in the glands of the neck in 5; in the abdomen in 5; and on the skin in one. This suggests that invasion of the pelvis had taken place by the hematogenous route in at least 52 of these patients. Evidence of the site of the primary lesion was available in 20 patients who had had tuberculous peritonitis. In only one out of every four of these patients was this site within the abdomen. It would therefore appear probable that peritonitis had arisen in at least 75% of these patients as the result of spread of infected material from a preexisting tuberculous focus in the pelvis. The human strain of tubercle bacillus was found in all patients from whom a successful culture was obtained. The date of primary infection was identified in 37 patients. In some, invasion of the pelvis occurred within a few months after the primary infection, and in more than half of the patients there was evidence that pelvic infection had taken place within three years of the primary infection. Dissemination to the pelvis probably occurs in the period of activity of primar tuberculous lesions. Genital tuberculosis was shown to be particular risk accompanying primary tuberculosis during ado lescence. This provides additional grounds for urging that girl be rendered tuberculin positive by BCG inoculation befor reaching this age.

A Study of the Effects of Dihydroergotamine on the Inta Human Uterus: Part I—"Sympatholytic" Properties. W. Garrett. J. Obst. & Gynaec. Brit. Emp. 62:145-149 (Apr 1955; **Part II—"Oxytocic" Properties.** M. P. Embrey and W. Garrett. ibid. 62:150-154 (April) 1955. [London, England].

Excess endogenous epinephrine and over-action of the uteri sympathetic nerves have been regarded as causal factors incoordinate uterine action, and so dihydroergotamine has he favor with some workers, as it is said to possess powerf epinephrine-blocking properties yet to be devoid of the oxyto activity characteristic of the ergot series as a whole—an activi that is potentially dangerous in labor because of the unpredi able spasm that it may produce. A study of the history of hydroergotamine shows that at its introduction to clinical pra tice it was hailed as a boon in the treatment of uterine inert Later, with further experience, a note of caution was sound Of the two reports presented here, that by Garrett is concern with its "sympatholytic" properties. He demonstrates that in t maximal dosage permissible in the human subject, dihyd ergotamine fails to impede the normal response of the body the uterus to the adrenal medullary hormones. After int muscular injection of 0.25 mg. of dihydroergotamine both e nephrine and norepinephrine still have their characteristic effe on the uterus in late pregnancy and labor; in the presence 0.1 mg. of dihydroergotamine per half hour by slow intraven infusion uterine contractions are still inhibited by epinephri From the human subject in late pregnancy and labor, dir tocographic evidence has been produced showing that dihyd ergotamine fails to block the actions both of epinephrine a norepinephrine in the doses recommended by its advocates. vestigating the "oxytocic" properties of dihydroergotami Embrey and Garrett present tocographic evidence from healthy puerperal patients that dihydroergotamine is a pow ful, though somewhat unreliable, oxytocic agent. The dose dihydroergotamine, if used as an oxytocic in the third stage labor, would be 0.75 to 1 mg. by intravenous injection, and least twice as much by intramuscular injection; but for this it does not appear to have any advantage over the bett established alkaloids. The strong oxytocic properties of dihyd ergotamine make it a potentially dangerous drug for the tre ment of incoordinate uterine action in labor.

Question of Interruption of Pregnancy in Retinopathia Gra darum. A. Heydenreich. Zentralbl. Gynäk. 77:1-14 (No. 1955 (In German) [Leipzig, Germany].

Many investigators regard the retinopathy of pregnancy as indication for therapeutic abortion, the only problem to be cided being when it should be performed. Whereas some vocate immediate interruption of pregnancy, others advise th therapy of the underlying nephropathy or preeclampsia shou be tried first. Heydenreich believes that repeated follow- examinations, if possible for several years after the retinopath should supply the answer to this problem. At his clinic a typic albuminuric retinopathy of pregnancy with papillary edem hemorrhages, foci of exudates, and vascular changes was d tected in 17 of 129 women with toxicosis of pregnancy (13% Three of these patients had eclampsia and 14 had preeclamps In contradistinction to these organic vascular and retin changes, functional changes, in the form of spastic irregulariti of the caliber of the retinal vessels and mild papillary edem were observed in 35% of the women with pregnancy toxicos Two factors are of decisive importance for the development eyeground changes in toxicoses of pregnancy: the height of th blood pressure and the duration of the toxicosis. The author wa able to make follow-up examinations one to six years after de livery in 15 of the 17 women with retinopathy. He found tha the widely accepted opinion that retinopathy of pregnancy i no threat to the life of the woman is erroneous. On the basis o eyeground changes, blood pressure, and functional tests of the kidney, 60% of the women showed signs of a malignant nephrosclerosis. Interruption of pregnancy or induction of labor is indicated in women with retinopathy for the following reasons. 1. The prospects of restoration to normal decrease as the eyeground changes increase. 2. The various therapeutic measures instituted, even when the woman is hospitalized for several weeks, never improved the preeclampsia or renal changes. On the contrary, the pregnant organism often resorted to self-defense, in that premature birth resulted spontaneously. 3. A viable infant is more often attained by prompt interruption of pregnancy than by prolonged waiting. Sterilization is not necessary, since even rather old primiparas with a severe retinopathy pass through a second pregnancy without any signs of toxicosis or retinopathy. In those women in whom eclampsia or preeclampsia was not complicated by eyeground changes, or who showed only functional changes in the retinal vessels, follow-up examinations several years later revealed complete recovery, that is, the prognosis was favorable in these patients.

Physical and Psychic Preparation of Women for Childbirth. F. Lepage and G. Langevin-Droguet. Presse méd. 63:549-551 (April 16) 1955 (In French) [Paris, France].

The authors' results with 40 women prepared for childbirth in weekly classes during pregnancy compare favorably with those obtained in 40 unprepared women, with regard to time of expulsion of the fetus, flexibility of the perineum, use of forceps, and perineal injury. The method consists of muscular and breathing exercises, massaging to instill relaxation, instruction regarding the process of childbirth, and discussion of psychic problems. This procedure should never be termed "childbirth without pain." Painful contractions are normal and unavoidable in labor, but their effect can be lessened by proper preparation of the parturient. Fear can be eliminated or minimized, and maximal cooperation can be secured. Better results are obtained as treatment is started earlier. To safeguard the reputation of the method, it should not be tried in unselected patients. Tuberculosis, heart disease, hypertension, albuminuria, diabetes, toxic goiter, adnexitis, fibroma, and habitual abortion are contraindications.

PEDIATRICS

Therapeutic Misuse of Salicylate Compounds with Resulting Intoxication: A Report of Two Cases in Infancy. J. F. Keith Jr. North Carolina M. J. 16:141-144 (April) 1955 [Winston-Salem, N. C.].

The first of the two children was a 5-month-old girl, who was referred to the hospital by her physician because of abnormal respirations and cyanosis. Three weeks prior to admission the infant had had acute coryza. At that time she was treated, without the advice of a physician, with aspirin, Castoria, and "fever and cold medicine" obtained at a local drug store. The child improved temporarily, but five days later the symptoms recurred. The "fever and cold medicine" was continued. Five days prior to admission the baby began to "feel hot," became irritable, and ate poorly. Three days before admission diarrhea developed, and was treated with penicillin. She was given 80 mg. aspirin and tablets for the fever, and the mother continued to give the "fever and cold medicine." On the day of admission the infant had periods of collapse alternating with periods of extreme irritability. She received 10 or more of the aspirin tablets in the 24 hours preceding admission, in addition to the "fever and cold medicine." She was seen by the family physician four hours prior to her hospitalization. At that time she was comatose, exhibited marked hyperpnea, and was cyanotic. A tentative diagnosis of salicylate intoxication was made, before laboratory data were obtained, and treatment with oxygen and parenterally administered fluid was started. Twelve hours after admission the infant suddenly had a generalized clonic convulsion and became extremely cyanotic. She was treated with sodium phenobarbital and calcium gluconate. Within five minutes the convulsion was relieved and the color improved. Because of continued diarrhea, 350 cc. of Ringer's solution and 350 cc. of 5% dextrose in water were given intravenously. Clear fluids, offered frequently and in small amounts by mouth, were taken eagerly. In 72 hours the diarrhea abated, there was a marked decrease in the hyperpnea, and the urine was negative for acetone. At the time of discharge, on the sixth hospital day, physical examination was within normal limits. During the five days prior to admission the infant had received 75 mg. per pound per day of aspirin, in addition to what had been given over the preceeding three weeks. The second patient was a girl, aged 23 months, whose mother had been giving her one or two aspirin tablets daily since early infancy, "because they seemed to make her quieter." Nothing was known of the amount given in the days immediately prior to the admission, but a fairly large amount was given because of the child's irritability, in the misconception that aspirin has a sedative effect. Keith believes that while idiosyncrasies to salicylate do occur, the type of salicylism most frequently seen in children is a true intoxication. These cases usually represent the injudicious use of aspirin therapeutically in infants and toddlers. Occasionally, intoxication occurs in the toddler group as a result of the accidental ingestion of oil of wintergreen, which has a methyl salicylate concentration of 98%, 1 cc. of this being equivalent to 0.5 gm. of aspirin.

Decompression Treatment of Whooping-Cough: A Clinical Survey of 903 Cases. H. S. Banks. Brit. M. J. 1:1052-1055 (April 30) 1955 [London, England].

During the last five and a half years, 903 patients with whooping cough were treated by low air pressures in a decompression chamber at the Park Hospital in London, England. The selected patients, up to six or eight at a time, went into the chamber accompanied by a nurse, ward orderly, or the parent in the case of some infants or a young frightened child. A telephone connected the occupants of the chamber with the porter-operator, who watched them through a porthole window during the whole course of the treatment. The pressure of air in the chamber was reduced progressively for about 20 minutes until the equivalent of an altitude of 12,000 ft. (3,660 meters) was reached. This low pressure was maintained for 45 minutes and then gradually increased during the 20 to 25 minutes "descent." The treatment thus lasted about 90 minutes. Some pain in the ears and deafness were commonly experienced during the "descent" and for a short time thereafter. Of the 903 patients, the results could be assessed in only 782, 63 of whom were less than one year of age, 454 were between the ages of 1 and 4, 244 between the ages of 5 and 9, 7 between the ages of 10 and 15, and 14 were aged 15 or over. Pronounced and rapid improvement in four to seven days with virtual cessation of the paroxysmal cough occurred in 205 patients (28.2%), and slower but probably significant improvement in 7 to 10 days occurred in 248 patients (34.1%), while 274 patients (37.7%) were therapeutic failures. A particularly valuable sequel to the treatment in many patients was the relief of vomiting; among the 427 children who were vomiting food more than once daily just before treatment, the vomiting stopped fairly abruptly in 246 (57.7%), was reduced in an additional 86 (20%), and was unrelieved in 95 (22.3%). Results in relation to the age of the patients suggested that children in the age group between 5 and 9 years may be benefited most by the decompression treatment, while results in infants and adults may not be quite so good as in children between the ages of 1 and 9 years. Twenty-four patients received a second decompression treatment, and although the figures are small they suggest that a second treatment did not often yield good results when the first treatment failed, except, perhaps, when the first treatment was given too early, i. e., before two and a half weeks of the disease. Decompression treatment is harmful to the acutely ill patients with pyrexia, cyanosis, or appreciable atelectasis. The results reported are based on careful selection of cases and combined assessment by parents and physicians. An adequately controlled experiment has not yet been done but should be attempted when opportunity offers. The mechanism of the action of decompression in whooping cough has not been elucidated. Further trials should preferably include biochemical studies.

New Therapy of Scoliotic Postures in Children. J.-B. Baron, A. Cabau and N. Cabau. Presse méd. 63:574 (April 20) 1955 (In French) [Paris, France].

Scoliosis in nine girls was corrected or improved by the wearing of prismatic lenses to correct heterophoria. Each patient had scoliotic posture, exophoria, lateral inclination of the head, and a lateral deviation on walking. The correction of the ocular disturbance by means of prismatic lenses immediately caused replacement of the sagittal axis perpendicular to the horizontal. This was accompanied by replacement of the sagittal axis of the head in relation to the vertical, raising of the dropped shoulder, and equalization of the brachiocephalic triangles. This phenomenon demonstrates the existence of synergy between the oculomotor muscles and the paravertebral muscles. It also offers a simple method for the correction of scoliosis, which can be prolonged indefinitely.

Effect of Administration of Gluten, Starch, and Fat on Children with Celiac Disease: Clinical and Experimental Investigations: Preliminary Report. C. Hansted. Ugesk. læger 117:481-493 (April 21) 1955 (In Danish) [Copenhagen, Denmark].

The author confirmed the observation that gluten from wheat, rye, and oats is harmful for children with celiac disease, while wheat starch, corn meal, rice flour, buckwheat, peas, beans, potatoes, various vegetables, meat, and fish are well borne. The patient's sensitivity to gluten depends on the kind and amount of fat in the diet. The sensitivity is greatest with a high fat content and greater with milk fat than with olive oil, which consists mainly of triglycerides with unsaturated fatty acids. The clinical symptoms on a gluten-free but high fat diet suggest that fat alone may to some degree unfavorably affect children with celiac disease. The gluten sensitivity is the same in a diet free from starch as in a diet rich in starch.

OPHTHALMOLOGY

Intravenous Treatment of Optic Neuritis: Comparison of Corticotropin and Typhoid Bacilli. P. Kazdan and R. J. Kennedy. A. M. A. Arch. Ophth. 53:700-701 (May) 1955 [Chicago].

Two groups of patients with optic neuritis who, at the time of treatment, were not thought to have a demyelinating disease were treated. One group of 11 patients was treated with intravenous injections of killed typhoid bacilli and the other group of 11 patients with intravenously administered corticotropin. There was no case of bilateral optic neuritis in the group treated with corticotropin; however, there were two such cases in the group treated with intravenous typhoid bacilli. One patient treated with corticotropin had a relapse five weeks after the last treatment. He was given a second course of 10 daily doses of intravenously injected corticotropin, followed by a tapering off with 25 mg. of oral cortisone four times a day for two weeks. A 13-month follow-up after the second course of treatment revealed no recurrence. Comparison of the results obtained from these two methods of treatment showed no superiority of one method over the other, especially as regards visual acuity.

New Theories of Vascular Disease, with Special Reference to the Syndrome of Polycythemia in Ocular Pathology. H. L. Birge. Am. J. Ophth. 39:362-369 (March) 1955 [Chicago].

The syndrome of polycythemia, including not only the rare polycythemia vera but also the common secondary types, has yet to be placed in its proper position as a cause of many vascular problems. Many ocular hemorrhages can be avoided by normalizing blood volume, and many vascular accidents can be prevented by learning to recognize the syndrome of polycythemia. If it is not recognized before ocular surgery, hemorrhage, hyphema, thrombosis, or anesthetic difficulties are likely to ensue. Polycythemia occurs more often in private than in clinic practice. It is most frequent in men between 50 and 60 years of age. Birge illustrates the importance of blood volume studies for ophthalmologic surgery on the basis of case histories. Blood-volume estimation should be routine in all cases in which the hematocrit report shows any abnormality whatsoever. Thrombosis is so common in patients with polycythemia that, when the ophthalmologist sees engorged, cyanotic retinal veins, he is justified in obtaining a hematocrit and, if the values are above 44 in females or 47 in males, he should order a blood volume determination. This practice will prevent many vascula accidents. When middle-aged persons have polycythemia due t dietary excesses, the simplest form of treatment is the prop diet. When treatment for the polycythemia syndrome must b administered quickly, phlebotomy is the method of choice. Thi procedure may be used for long-term treatment if it is repeate at the required intervals. Radioactive phosphorus (P^{32}) is pr ferred by hematologists in cases of polycythemia vera. The u of anticoagulants involves many problems, such as the expensiv ness of heparin, or frequent prothrombin time tests, if oth anticoagulants are used. Birge therefore does not favor an coagulant therapy but suggests more frequent study of t blood volume, with changes in the blood elements as indicate This therapy seems to give better results with less danger a at less expense than anticoagulant therapy. By reducing t excessive blood volume, the problem can be handled simply the office, and proper attention can be given to such seconda factors as hypertension, diabetes, or cardiac failure.

Vogt-Koyanagi Syndrome Precipitated by Lens Extracti Report of a Case. E. A. Swartz. Am. J. Ophth. 39:488-4 (April) 1955 [Chicago].

Swartz presents the history of a man, aged 55, in whom extracapsular lens extraction was done for a hypermat cataract, with accidental rupture of the capsule. Subseque bilateral uveitis, alopecia, poliosis, vitiligo, and dysacousia veloped. While this combination of symptoms has long b known as the Vogt-Koyanagi syndrome, it has never been ported in its entirety as the result of intraocular surgery. positive pigment test, along with the bilateral uveitis follow surgery, is consistent with the diagnosis of sympathetic ophth mia. Swartz feels that sympathetic ophthalmia and the V Koyanagi syndrome (which he would call uveoencephalitis agreement with Cowper) are basically the same entity and the same etiology, although the etiological factor need not the same agent in all instances. He gained the impression t the two conditions are related like mirror images, in that in so-called Vogt-Koyanagi syndrome the etiological agent ga entrance to the cranial contents and progresses thence to the whereas, in the sympathetic ophthalmia form, the etiolog agent gains entrance to the eye and progresses from there the cranial contents. Penicillin, aureomycin, and terramy were not beneficial in the treatment of this case. Cort applied topically and subconjunctivally was of slight benefit long as it was used but did not bring about complete quiesce of the disease process.

Experimental Approach to the Pathogenesis of Retrole Fibroplasia: II. The Influence of the Developmental Matu on Oxygen-Induced Changes in the Mouse Eye. L. J. Gyll sten and B. E. Hellstrom. Am. J. Ophth. 39:475-488 (Ap 1955 [Chicago].

Newborn mice and 5-day-old and 10-day-old mice w exposed to 98% or 100% oxygen for five days, after which t were rapidly transferred to normal air. They were killed fr 1 to 10 days later, and the eyes were subjected to microsco examination. All groups of mice showed hemorrhages in eyes, mostly in the nerve fiber layer and in the vitreous bo There were irregular proliferations of the nerve-fiber vess with capillary tufts budding into the vitreous body, and regularities of the retinal layers. In newborn mice the reti changes were mostly concentrated in the neighborhood of t optic disk; in older ones they reached more anterior parts the retina also. The ocular hemorrhages and the irregular vas proliferation were more conspicuous in mice exposed to co centrated oxygen at an earlier age than in those exposed oxygen at a later age. The older animals tended to show mo retinal irregularities and foldings than the younger ones, a an increasing frequency of a characteristic retinal atrophy the ganglionic layer, the inner nuclear layer, and the outer plex form layer was observed. These experiments seem to provi further evidence of the pathogenetic relation of the oxyge induced eye changes of mice and human retrolental fibroplasi

THERAPEUTICS

A Method for the Objective Evaluation of Bronchodilator Drugs: Effects of Dapanone, Isuprel, and Aminophylline in Patients with Bronchial Asthma. L. Cander and J. H. Comroe Jr. J. Allergy 26:210-218 (May) 1955 [St. Louis].

Seventeen asthmatic patients between the ages of 18 and 67 years were asked to inspire fully and then to expire as rapidly and forcefully as possible into a well-balanced spirometer writing with minimal friction on a rapidly moving kymograph. This procedure gives values for both vital capacity and maximal expiratory flow rates. The test measures objectively the degree of bronchial or bronchiolar obstruction. The technique is rapid and simple and requires a minimum of understanding and cooperation on the part of the patient. After several control tests, drugs were administered. On one day, isopropylarterenol (Isuprel) hydrochloride (1:200 aerosol) was administered first, followed 30 minutes later by 3,4-dihydroxyisopropylamine propiophenone (Dapanone) hydrobromide (2% or 5% aerosol); on another day, the order was reversed. The dose of the aerosol administered over a 10-minute period varied between 0.2 and 0.4 cc. Vital capacity and maximal expiratory flow rate were measured at 5-minute and 10-minute intervals during the next 30 minutes. In all cases, 0.5 gm. of aminophylline was given intravenously over a 10-minute period after the administration of the two other drugs. Results indicated that either 5% Dapanone or 0.5% Isuprel, given initially as aerosol, is an effective bronchodilator drug. Each drug produces a significant increase in maximal expiratory flow rate if administered after time has elapsed for maximal action of the other drug, administered first. The peak effect occurred in almost every patient within 30 minutes after the administration of these drugs. Maximal benefits, however, were obtained by the simultaneous use of these nebulized drugs and aminophylline, administered intravenously. Data obtained in the authors' study on the variability in vital capacity and maximal expiratory flow rate in asthmatic patients without therapy reemphasize the need for careful control studies in the evaluation of bronchodilator drugs.

Study of Framycetin Sulfate in Aerosol Therapy in 198 Cases of Bronchopneumopathy. A. Biron. Presse méd. 63:551 (April 16) 1955 (In French) [Paris, France].

The author administered framycetin sulfate in aerosol form to 198 patients with bronchial asthma, tuberculous asthma, lung abscess, suppurating bronchitis, acute bronchitis, or pulmonary congestion. Results were good in 172, fair in 21, and poor in 5 patients. There were no instances of drug intolerance in the usual dosage of 100 mg. a day nor in doses ranging from 300 to 600 mg. a day. The highest total dose given was 18 gm. in 30 sessions. Thus framycetin sulfate in aerosols seems to be an efficient, safe method of dealing with certain pathogenic agents not easily influenced by other forms of therapy, such as resistant micrococci, and proteus or pyocyanic organisms.

Long-Continued Anticoagulation Treatment with Phenindione. P. Jorde. Nord. med. 53:604-605 (April 14) 1955 (In Norwegian) [Stockholm, Sweden].

From October, 1941, to October, 1954, 30 patients were given long-continued anticoagulation treatment with phenindione on an ambulant basis. In 12 cases the diagnosis was cardiac infarct, in 11, angina pectoris, and in 7, thrombosis or embolism. Phenindione lends itself well to long-term anticoagulation treatment under ambulant control. The dosage for ambulant patients is higher than for hospitalized patients. The effect is fairly stable and an even prothrombin-proconvertin level seems to be more easily maintained with a constant dose of phenindione than with dicumarol. The duration of treatment averaged 339 days. In most patients the prothrombin-proconvertin level fluctuated between 10 and 30%. In some there were peaks beyond the 30% limit, as a rule because of need for increased phenindione dosage. Complications occurred in two patients; melena in one and hematoma in a whitlow in the other. The patients are warned that they must not undergo an operation without control of the prothrombin-proconvertin level.

Anticoagulants of Dicumarol Type: Clinical Experiments with Different Preparations. E. Lund, T. Geill, E. Søndergaard, and H. Dam. Nord. med. 53:602:604 (April 14) 1955 (In Norwegian) [Stockholm, Sweden].

Marcoumar, dicumarol, and the Geigy preparations—tromexan, coumachlor, G. 25766, and G. 23350—were tested with respect to their efficacy in the treatment of thromboembolic diseases. The anticoagulant effect was determined according to Aas's modification of the Owren and Aas prothrombin-proconvertin method. Dicumarol was found to have the well-known effect described in the literature. The dosage of tromexan was difficult to regulate because of the great variations in the prothrombin-proconvertin values. Coumachlor has a powerful protracted effect; the dosage was difficult to regulate because of strong individual differences in tolerance. The effect of G. 25766 was also prolonged; the dosage was easy to regulate, and it is regarded as well adapted for clinical use. The action of G. 23350 is like that of dicumarol. Marcoumar exerts a prolonged effect, readily allows the prothrombin-proconvertin values to be kept within the therapeutic range for a longer time with constant dosage, and is well suited for clinical use. Intravenous administration of moderate amounts of vitamin K_1 in aqueous colloidal solution produces a sure and rapid effect on prothrombin-proconvertin activity, which is reduced as the result of treatment with dicumarol and like preparations. If grave bleeding has set in, 10 to 20 mg. of vitamin K_1 should be given intravenously as an antidote. The therapeutic effect is attained in the course of two hours. If vitamin K_1 is given orally, the effect appears after five or six hours. If the anticoagulation treatment resulted in prothrombin-proconvertin values lower than 10% and thus caused a latent risk of hemorrhage, the prothrombin-proconvertin activity can readily be brought into the therapeutic range by small daily oral doses (1 to 2.5 mg.) of colloidal vitamin K_1.

Intermittent Isoniazid Treatment. I. Seri, E. Fehérvári and I. Szabó. Beitr. Klin. Tuberk. 113:234-240 (No. 3) 1955 (In German) [Berlin, Germany].

Intermittent treatment with isoniazid given on three consecutive days followed by a four day drug-free interval was given a trial in mice and men. Intermittent treatment of the animals was started with a daily dose of 15 mg. of isoniazid per kilogram of body weight on the first day after they had been inoculated with tubercle bacilli strain H 37 Rv. The intermittent treatment protected the animals against the development of tuberculosis in the same degree as the daily treatment with isoniazid did. Sixty patients with pulmonary fibrocavernous tuberculosis were given intermittent treatment with isoniazid at the State Tuberculosis Hospital in Budapest, Hungary. On three successive days the patients received a daily dose of 10 mg. of isoniazid per kilogram of body weight and in addition 10 to 16 gm. of *p*-aminosalicylic acid. In the next four days the patients did not receive any of the two drugs. This course of treatment was continued for 18 weeks. The results of the intermittent treatment in these patients were compared with those of the daily treatment of 50 patients with pulmonary tuberculosis with 5 mg. of isoniazid per kilogram of body weight and 4 to 12 gm. of *p*-aminosalicylic acid for 16 weeks. Results obtained with the intermittent treatment were superior to those with daily treatment since there was more pronounced roentgenologic improvement in general and concerning the cavities, the sputums of a larger number of patients became negative, and the improvement in the sedimentation rate was more pronounced. Development of resistance to the drug was slower, and the patients were able to tolerate larger doses of *p*-aminosalicylic acid. In the presence of moderate resistance, when small doses were no longer effective, improvement was still obtained with intermittent administration of the drugs. The incidence of undesirable side-effects was not higher with intermittent than with daily treatment. Consequently, this method of treatment is recommended for patients who are in the subacute stage of the disease and who require prolonged treatment.

BOOK REVIEWS

Advanced Surgery of Cataract. By Daniel B. Kirby, M.D., F.A.C.S., Surgeon, Department of Ophthalmology, University Hospital, New York. Cloth. $27. Pp. 271, with 234 illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; 2083 Guy St., Montreal, Canada; distributed by Pitman Medical Publishing Company, Ltd., 39 Parker St., Kingsway, London, W.C.2, England, 1955.

In this book Dr. Kirby focuses attention on some of his newer approaches, advanced ideas, theories, and techniques, beginning with the complete preparation of the cataract patient by individual appraisal. He emphasizes the importance of sedation, anesthesiology (local or curare), and attention to the operating room equipment, medications, and sterility. His comments on the attitude and psychological approach of the ophthalmologist and operating room personnel illuminate a phase in cataract surgery often overlooked. He stresses the elevation of the corneal flap for clear, direct visualization of iris details, the cataract, the zonular attachment, and their attachments to the preequatorial area of the capsule. He considers the indications and reasons for the round pupil intracapsular lens delivery with the forceps at the 12 o'clock position in the preequatorial region. His chapter on the normal and pathological vitreous and its physico-chemical state is revealing and informative. He discusses the postoperative degeneration of the vitreous due to trauma to the vitreous and adjacent structures. He strongly advises against the use of undue and excessive pressure to separate the zonule and deliver the lens. He has developed a new and original explanation of the mechanics of the pressure maneuvers based on fundamental research and has redefined the variations of traction, force, the effects of the direct pull, elevation, tension, and sliding rotation. The surrations seen near the equator of the lens when traction is made on the lens capsule are also described. These serve as a guide against undue traction. One of the highlights of the book is the description of the procedures in the direct separation of the zonule above with a minimal amount of trauma and with a vitreous loss of slightly over 1%. The author reports having removed 97% of the lenses in capsule. Only by reading this abundantly illustrated and crystal clear description of the many newer concepts and techniques of cataract surgery can the ophthalmologist be made aware of the detailed and intimate interpretation of the phenomena occurring during cataract operations.

Doctors in the Sky: The Story of the Aero Medical Association. By Robert J. Benford, M.D., Colonel, Medical Corps, United States Air Force. Cloth. $8.75. Pp. 326, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, Canada, 1955.

This is the story of the first 25 years of the Aero Medical Association and its growth from a group of 35 men in 1929 to the prominent organization it is today. The book pays tribute to Dr. Louis A. Bauer, founder and first president of the association, a one time military flight surgeon who organized the first school of aviation medicine and wrote the first book on this subject. There are chapters on aviation medical journalism, medicine and air commerce, flight surgeons for airlines, and the recognition of aero medicine as a specialty. Interwoven into these chapters are biographical sketches of all the past-presidents of the association and a description of its annual meetings. Appendixes list the meetings, presidents, fellows, honorary members, certified specialists in aviation medicine, and others who in one way or another have achieved special prominence. The constitution and bylaws of the association are reprinted, and a selected bookshelf of aviation medicine is given. The illustrations are well selected but of uneven quality. The index consists chiefly of the names of military and civilian flight surgeons. The book will probably be of limited interest to those who are not closely associated with aviation medicine.

Handbook of Parliamentary Procedure. By Henry A. Davidson, Parliamentarian, American Psychiatric Association, Cedar Grove, N. J. Cloth. $3.75. Pp. 292. Ronald Press Co., 15 E. 26th St., New York 1, 1955.

The author shows evidence of his medical training in that he not only names the "diseases" and tells the basic characteristics of each "disease" but also recites possible complications and tells how each one may arise and how it should be treated should it arise. This book is more of a reference book or textbook than a handbook. Examples of the use of rules and a discussion of the reason for and method of their use is a feature. The glossary with the definition of each technical term is invaluable. Although exact details in answering hypothetical questions with a discussion of other possible opinions is of great value to the beginner, the expert will also gain much in reading this book. It gives sense and understanding to "Roberts Rules of Order" and other standard works that are commonly misinterpreted. The discussion of the difficult problem of substitute motions, often encountered in dealing with the so-called minority reports of committees is especially interesting. The lucid and logical explanation of many of the most troublesome rules will tend to increase the efficiency of every chairman who reads the book. This book not only instructs the chairman but also tells the members of an assembly how to accomplish their purposes and how to protect their rights. In fact, after reading this book a "sea lawyer" will know more than many able chairmen.

Bickham-Callander Surgery of the Alimentary Tract. Volumes I, II, and III. By Richard T. Shackleford, M.D., Assistant Professor of Surgery, Johns Hopkins University School of Medicine, Baltimore. Assisted by Hammond J. Dugan, M.D., Assistant in Surgery, Johns Hopkins University School of Medicine. [Second edition.] Cloth. $60. Pp. 862; 863-1633; 1635-2575; lxxxix, with 1705 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1955.

In the foreword, the author, who was once associated with the late Dean Lewis, states that he accepted revision of Bickham's Operative Surgery with "a considerable amount of trepidation." After passing the second chapter, one can state that his uncertainties were not well founded. He shows fearless, positive, and thorough knowledge of all segments of surgery. He supports his point of view with a well-chosen, authoritative, and current bibliography, at the end of each chapter. The results of surgical procedures are stated. A succinct comment follows each description. The illustrations are well executed, properly placed, and have excellent legends. This type of book finds its greatest need in outlying communities, far removed from our teaching centers. Volume 1 deals with the esophagus, stomach, duodenum, liver, gallbladder, and extrahepatic bile ducts; volume 2 with the pancreas, spleen, small intestine, peritoneum, omentum, mesentery, and colon; and volume 3 with the anorectal tract, excision of the rectum, hernia of the gastrointestinal tract, and incisions. The author has handled a difficult assignment very well.

Heart Disease: Its Diagnosis and Treatment. By Emanuel Goldberger, M. D., F.A.C.P., Associate Attending Physician, Montefiore Hospital, New York. Second edition. Cloth. $12.50. Pp. 781, with 107 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1955.

In this edition Dr. Goldberger has retained the same general pattern as in the first edition, but with a number of changes and additions. Chapters that have been revised and expanded are those on heart failure, congenital heart disease, cardiac surgery, hypertension, and myocardial infarction. A new chapter on ballistocardiography has been added. Dr. Goldberger, who is probably best known for his work on unipolar electrocardiography, has resisted the temptation to overemphasize that phase of cardiology and has written a well-balanced, up-to-date, standard book on heart disease as a whole. It is well illustrated. At the end of each chapter there is a well-selected bibliography. This volume is recommended as a textbook for medical students and interns and as a reference book for the general practitioner.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUERIES AND MINOR NOTES

LL-OUT RADIATION

THE EDITOR:—*The Atomic Energy Commission stated recently that the amount of radiation due to fall-out was not greater than that affected by subjecting a person to a chest x-ray examination. Is not the distribution of the fall-out radiation at times irregular due to such factors as shifts of winds and precipitation so that even distant localities may get more radiation than those closer to the explosion? What about the amount that is added to the rest by the consumption of exposed water, crops, and livestock?* *M.D., New York.*

ANSWER.—With regard to the distribution of fall-out radi-on, there are marked variations due to winds, precipitation, d the like. The Atomic Energy Commission maintains a broad twork of measuring stations. Studies of water, crops, and live-ock have been and are being carried out very widely. As yet, off-site levels of radiation equal to those received during a est x-ray examination have been found nor is it likely that such ll be the case in light of the careful plans made by the Atomic ergy Commission and its scientists for the carrying out of tests.

UTPATIENT SHOCK TREATMENTS

THE EDITOR:—*A psychiatric patient has received shock treatments in a mental hospital with improvement, and it has been suggested that he receive the shock treatments on an outpatient department basis. Is shock therapy to be recommended on an outpatient department basis?*

Francis J. Petrone, M.D., Fall River, Mass.

ANSWER.—Some psychiatrists administer shock treatments to bulatory patients in outpatient offices and in private offices. nce the shock treatment is followed by a period of confusion, e patient must be accompanied by someone capable of waiting r his recovery from the postshock confusion and able to take e patient home. Many psychiatrists completely reject ambula-ry shock treatment, since the many possible complications and quelae of shock treatment are not under their observation or ntrol if the patient then goes home. There is a sharp division opinion about the matter, and this consultant would caution at anyone who does ambulatory shock treatment takes an necessarily dangerous responsibility for which there may be bilities for serious medical-legal prosecution.

UTURE MATERIAL FOR CORRECTION OF NGUINAL HERNIA

THE EDITOR:—*In the repair of an inguinal hernia, direct or indirect, some surgeons use stainless steel for sutures. What is the consensus on the use of steel sutures? Are they superior or inferior? Can their use be harmful from a long-range point of view?* *M.D., New York.*

ANSWER.—Although there is no complete consensus as to hat type of suture material should be used for correction of guinal hernia, it is the opinion of this consultant that the ajority of surgeons believe stainless steel sutures are of little enefit in the performance of a hernioplasty. There is a general onsensus, however, that nonabsorbable suture should be used, nd apparently there is about an equal division among those articularly interested in the subject about the advisability of e use of cotton or silk. It is generally agreed that absorbable atgut) sutures should not be used, because of the greatly in-eased reaction in any wound when absorbable sutures are used. Although stainless steel produces no reaction, it is probably undesirable for a radio-opaque material to be left within the abdominal wall. If the individual is thin, the sutures can frequently be felt, which is occasionally of psychic importance, and at times the sutures produce discomfort or real pain. Certainly, if reoperation becomes necessary, which is occasionally the case in spite of the type of suture material used, operation is much more difficult if stainless steel has been used at the previous procedure. This consultant is of the opinion that stainless steel has no advantage over the other nonabsorbable material, such as cotton or silk, and it has definite disadvantages in that it is more difficult to use and remains behind as a palpable and radio-opaque suture.

DIZZINESS IN SAILOR WHILE ON LAND

TO THE EDITOR:—*A 43-year-old white man complains of dizziness. He has resigned from the Merchant Marine after eight years' service. He states that while aboard ship at sea he was never bothered by dizziness; however, on going ashore he began to notice dizziness. Since he has been land based for eight months the dizziness has become progressively worse. There are no essential findings that could explain this. Blood pressure is 140/100 mm. Hg, the heart and lungs are normal, and the genitourinary, cardiorespiratory, and gastrointestinal systems are normal. He recently had an adenoidectomy and plastic surgery of the nose for nasal obstruction due to an old fracture. He had a chronic mild otitis media in the past, but it is not active now. Could this represent an imbalance of the vestibular system as a result of the constant rolling and pitching of a ship at sea? Treatment at present is dramamine, 50 mg. three times a day, and a low-salt diet.*

Jonathan P. Shermer, M.D., Fort Smith, Ark.

ANSWER.—Dizziness of peripheral vestibular origin may be the result of labyrinthine hydrops (Ménière's disease), labyrinthine injury by fracture or concussion, or interruption of the arterial blood supply to the labyrinth. In all of these conditions the vertigo is associated with nystagmus, nausea, vomiting, and ataxia, and in most of them there is also a perceptive hearing impairment. In labyrinthine hydrops the vertigo is characterized by recurring attacks with comparative freedom from dizziness between attacks. In the other conditions mentioned there is a single attack of vertigo lasting a few hours or days followed by gradual recovery. In the case described, where the dizziness is continuous, it is unlikely that it is due to peripheral labyrinthine disease. It is more likely due to a central disturbance such as multiple sclerosis or a psychogenic factor. It is not conceivable that dizziness lasting eight months could be the result of the motion of a ship at sea.

HEPARIN-LIPOTROPIC THERAPY

TO THE EDITOR:—*Please comment on heparin-lipotropic therapy as discussed by Read and Obetz in an article in the* Ohio State Medical Journal, *March, 1955.* *M.D., Wisconsin.*

ANSWER.—Therapy directed at a reduction of serum lipids, and particularly of the low density (beta) serum lipoproteins, is logical in view of present knowledge of the pathogenesis of atherosclerosis. Although other factors, such as blood pressure and local factors in the vascular wall are undoubtedly important, the evidence is fairly conclusive that the circulating lipoproteins are the source of the increased lipids found in atherosclerotic vascular walls. The physical state and particle size of the lipoproteins are important (in agreement with the older macromolecular theory of Hueper), probably due to the filtration properties of the vessel walls. The injection of heparin results in the formation of lipemia-clearing factor, or heparin-active factor, and a rapid decrease in the concentration of the larger low density (beta) lipoproteins. There is a reduction of the total

---

The answers here published have been prepared by competent authori-es. They do not, however, represent the opinions of any medical or other rganization unless specifically so stated in the reply. Anonymous com-unications and queries on postal cards cannot be answered. Every letter ust contain the writer's name and address, but these will be omitted on quest.

amount of fat in the blood stream. Studies of most cell counts in animals and humans, and of circulating heparin levels, indicate that decreased heparin production in the body may be etiologically important in the accumulation of large amounts of circulating low density serum lipoproteins. Heparin retards the development of atherosclerosis in cholesterol-fat fed animals. However, reports of the effect of heparin therapy in angina have been contradictory. It must be remembered, however, that angina is a manifestation of preexisting disease. The product mentioned, Hepnine B, combines heparin, so-called lipotropes, and vitamin B factors. The preponderance of evidence negates any effect of added lipotropic substances on plasma lipids. The amount of heparin (25 mg.) in 1 cc. of the product is rather small, too little for marked or protracted anticoagulant or antilipemic effect. It is stated in the article quoted that choline negates the anticoagulant action of the heparin, but no data are given. The changes in the Sf 0-400 lipoproteins mentioned in three cases are unconvincing. In the first two cases—patients with diabetic gangrene and postacute myocardial infarction—the lipoproteins may have been reduced by active tissue necrosis and stress. The slight lipoprotein drop in the third case could easily be a spontaneous variation. Thus the beneficial effects noted were in angina, a most deceptive symptom. In view of the very small amounts of heparin given (25 mg. twice weekly) and in the light of present knowledge, it is hard to understand the mechanism responsible for the beneficial effects that were reported. Considerably larger amounts of heparin are required for prolonged marked reduction of plasma lipemia or lipoproteins.

WEIGHT REDUCTION

To the Editor:—*A man, 49 years of age, height 5 ft. 3 in., weighs 194 lb. He has taken off weight by a very hard diet; about 20 lb. His heart is normal, and the electrocardiograph does not show any pathological changes. His basal metabolic rate is plus 20. He lives on a diet of about 1,000 calories daily, but the weight does not go down further. What would you recommend in this case?* *Nathan Roos, M.D., New York.*

Answer.—A man who is 5 ft. 3 in. and weighs 194 lb. would have a basal metabolic caloric need of 1,600 to 1,900 calories. Nothing has been said of this patient's activity. It seems highly improbable that this patient is maintaining a constant diet of 1,000 calories and cannot lose weight. If it is at all possible, a week's hospitalization where the patient can be given a weighed 800 to 1,000 calorie diet and at the same time receive considerable dietary instruction and counseling might start the patient to lose weight again and thus encourage him. After discharge from the hospital it might be a good idea if he indulge in some light exercise regularly in addition to his dieting and, as an adjunct to his regular visits to his physician, to make regular bimonthly visits to a nutritionist who will spend time discussing his diet difficulties and give him understanding and encouragement. The motivation to lose weight must be there before anyone can continue on any restricted diet. This motivation must be kept alive, and the physician and nutritionist will have to help do this. Diet lists alone are not enough.

DIET AND PHYSICAL ENDURANCE

To the Editor:—*Can an alkaline diet hasten recovery from strenuous physical exertion? Can a preponderance of acid foods in the diet have an adverse effect on physical efficiency, endurance, or recovery from exertion?*

Nathaniel Sharp, M.D., Baltimore.

Answer.—As far as known there is no evidence that an "alkaline-ash" diet or "acid-ash" diet can affect efficiency and endurance. Diets are considered acid or alkaline by nature of the mineral residue they leave after combustion in the body. Meat, eggs, cereals, and cheese are the main acid-ash foods, while vegetables, most fruits, and milk are the main alkaline-ash foods. The body has an excellent buffer system, and the pH is very difficult to alter by dietary means. The pH of the urine can be acid, but this or the alkalinity of the diet has no known effect on physical endurance.

SCHOOL SHOWER FACILITIES

To the Editor:—*Are so-called gang or private shower facilities preferable for girl students in junior and senior high schools? Our high school has only two shower cubicles, and the rest of the shower facilities are without partitions. The school authorities have been advised that shower facilities without partitions are proper for girls of high school age, but some parents are not in favor of "gang" shower facilities.*

M.D., Connecticut.

Answer.—Whether "gang" showers or "stall" showers should be constructed in the shower facilities for girl pupils in junior and senior high schools depends on the self-consciousness and modesty of the pupils. Experience has shown that, in constructing a battery of showers, it is advisable to have the majority of them as "gang" showers, with one or two, or some other small proportion commensurate with the size of the school, in private shower stalls. Most pupils prefer "gang" showers. One will invariably find a few pupils, boys or girls, who by reason of early training and habit, insist on privacy in the nude. However, the appeal of the group soon leads them to prefer the "gang" showers. The reason for wanting to shower alone may be a habit of years, it may be based on immaturity of development or some physical disability that may cause comment, or it may be that the individual is not socially inclined. Whatever the cause, a few stall showers should be provided to permit these individuals to enjoy recreational activities without unnecessary embarrassment. The great majority however should be "gang" showers, which are more efficient. Since they are in the open with a minimum of wall area, they are much easier to keep clean and free from odors. Likewise, dressing in a shower stall limits the number of persons using the shower and therefore requires more showers and a larger portion of the building devoted to shower facilities.

LEUKOPLAKIA OF CERVIX

To the Editor:—*A patient has leukoplakia of the cervix, which covers quite an extensive area. What is the best way of treating it?*

Howard T. Morse, M.D., Takoma Park, Washington, D. C.

Answer.—Leukoplakia of the cervix is likely to change in character or disappear without treatment. It is usually induced by irritation and consists of a simple hyperkeratosis with a slight increase in the activity of the basal layer of cells. In spite of the fact that cancer of the cervix has occurred in conjunction with leukoplakia, there is no evidence that it is a precancerous lesion. The patient should be observed periodically, and, if there is any question as to the diagnosis, cytological smears and a liberal biopsy will help.

PARALYSIS OF DIAPHRAGM

To the Editor:—*A boy, aged 7 years, was found to have a paralysis of the right side of the diaphragm on a routine chest x-ray. The lungs were reported within normal limits. The condition is asymptomatic as far as the child, who appears normal, is concerned. Kindly send me the latest information on this condition. Is surgery indicated?*

Morton Marks, M.D., Milwaukee.

Answer.—Idiopathic paralysis of the diaphragm is not uncommon. It goes under the term of "eventration of the diaphragm." As the word "idiopathic" suggests, its cause is not known. Apart from its relatively slight effect on vital capacity, it is not clinically significant. Prior to 1936, induced permanent paralysis of the diaphragm by extraction of the phrenic nerve was common treatment in pulmonary tuberculosis. People who had this treatment have suffered no important ill-effects. In a child adjustment to the condition will probably be very satisfactory, and the condition will probably never become clinical. The only treatment is thoracotomy with plication of the diaphragm. This lowers it and permits greater expansion of the lung with a consequent increase in vital capacity. In a child operation should possibly be considered.

THE JOURNAL

of the American Medical Association

Published Under the Auspices of the Board of Trustees

VOL. 158, NO. 13 CHICAGO, ILLINOIS JULY 30, 1955

COPYRIGHT, 1955, BY AMERICAN MEDICAL ASSOCIATION

THE PHYSICIAN AND WORLD MEDICINE

Harold S. Diehl, M.D., Minneapolis, Leonard W. Larson, M.D., Bismarck, N. D.
and
Franklin D. Murphy, M.D., Lawrence, Kan.

Health is a subject in which all people of the world, irrespective of color, race, and political philosophy, have a common interest. In fact, international cooperation in the field of health work may well prove to be a common ground for the development of understanding and cooperation that could extend to more difficult and controversial areas. This is a field in which the United States has the ability as well as a unique opportunity to assume world leadership. In the attainment of these objectives, physicians have very special opportunities and responsibilities. Fortunately, two organizations have been developed since World War II through which physicians may contribute to world health, world understanding, and world peace. These are the World Medical Association and the World Health Organization, organizations that constitute a team that is making one of the greatest contributions of our time to the improvement of mankind—a must for the prevention of the spread of communism. It is important that physicians understand the nature of each organization, its membership, its goals, and the individual physician's relationship to it.

THE WORLD MEDICAL ASSOCIATION

The World Medical Association is the world organization of physicians as a professional group. It is the equivalent on the world scene of the American Medical Association in the United States. It is composed of medical societies of the world, with the American Medical Association playing a leading role. In addition to association memberships, it allows for personal memberships on the part of physicians. The World Medical Association, which was founded after World War II at the initiative of leaders of the profession, particularly of the United States, Canada, England, and France, has grown in influence and importance as the voice of the physicians of the world. Annually, at its assemblies and at council meetings, it brings together leaders of organized medicine to consider the broad problems facing the physicians of the world. Among the contributions that the World Medical Association has made during its brief life are the development of the International Code of Medical Ethics, which is becoming increasingly well known as the modern Hippocratic Oath, and the sponsorship of the first World Congress on Medical Education, held in London in 1953, which has given stimulation and direction to the improvement of medical education throughout the free world. Currently it is undertaking leadership in the field of occupational health on a world-wide basis. Dr. Louis Bauer, past-president of the American Medical Association, is the executive secretary of the World Medical Association. Dr. Gunnar Gundersen and Dr. Edwin S. Hamilton, members of the Board of Trustees of the American Medical Association, are members of the council of the World Medical Association.

WORLD HEALTH ORGANIZATION

The World Health Organization is the governmental member of the world health team, analogous on the world level to the United States Public Health Service on the national level. It is a technical agency in the field of health, set up by the governments of the world within the general orbit of the United Nations, yet it is administratively independent of the United Nations. It has a membership of 84 nations. WHO is concerned with the improvement of public health and the development of sound and effective public health services in the nations of the world. It has established international services of great value, such as the compilation and dissemination of information concerning the prevalence of epidemic diseases and the development of international standards of biological preparations, services that can be provided only by an intergovernmental health agency. The policy-forming body of the World Health Organization is the World Health Assembly, which meets annually and is composed of delegations from the member governments. These delegations are always headed by physicians and, in the case of the United States, always include a representative of the American Medical Association.

Among the important accomplishments of the World Health Organization have been the exercise of leadership in the world-wide control of malaria, a disease that has long been of first importance in many countries of the world but that is now rapidly disappearing from the globe; leadership and direction in the mass control of yaws in the Carribean area and in Southeast Asia; the issuance of definitive technical reports of committees of international experts on a wide range of subjects, such as mental health, nursing, environmental sanitation, influenza, and plague; and the training through fellowship grants of some 2,000 professional persons in the field of health from countries that do not have facilities for needed training. The present director-general of the World Health Organization was elected by the World Health Assembly in 1953. He is Dr. Marcolino Candau of Brazil, who received much of his professional training in the United States and his public health experience with the Rockefeller Foundation and Institute of Inter-American Affairs Missions in Brazil. The chairman of the executive board of WHO is an American physician, Dr. H. van Zile Hyde, a Public Health Service officer who formerly practiced internal medicine in Syracuse, N. Y.

THE WORLD HEALTH TEAM

The World Medical Association and the World Health Organization work closely together, collaborate in various projects, and exchange representation at meetings of their various policy-forming bodies. The World Medical Association has been recognized formally by the World Health Organization as a spokesman for organized medicine in the world and is among the nongovernmental agencies given a formal status of relationship with the World Health Organization. It is essential that these organizations continue to cooperate in order to assure the greatest possible competence in areas such as the listing of drugs for which international standards are needed, the determination of dosages to be included in pharmacopeias, and the development of international practices affecting physicians.

At the national level in the United States, there is close association among those directly concerned with United States participation in each organization. As pointed out, the United States delegation to the World Health Assembly includes a representative from the American Medical Association. In addition to the three of us, such representation has included Dr. James E. Paullin and Dr. George Lull, members of the delegation that established the World Health Organization in 1946; Dr. James Miller, formerly a member of the Board of Trustees; Dr. E. J. McCormick, past-president of the A. M. A.; and Dr. Harry Mulholland, who has served the A. M. A. in many capacities. The chief of the delegation has always been a physician, the most recent being Dr. Chester Keefer, professor of medicine of Boston University medical school and special assistant to the Secretary of the Department of Health, Education, and Welfare. In 1953, the Board of Trustees of the American Medical Association established an International Health Committee to serve in a liaison capacity with the United States Public Health Service on international matters. This Committee is composed of the officers of the Board of Trustees, the secretary-general of the World Medical Association, and the representative of the American Medical Association on the preceding delegation to the World Health Assembly. This Committee has met three times with the chief of the Division of International Health of the Public Health Service and other governmental officials concerned with international health to hear reports on World Health Organization activities and to review and discuss matters coming before the World Health Assembly. This Committee preserves intimate and friendly relationships between governmental and nongovernmental agencies interested in this field.

THE INDIVIDUAL PHYSICIAN'S OPPORTUNITIES

There are several very definite things that American physicians can do to forward the work of both the World Medical Association and the World Health Organization as teammates on the world scene. Every physician who is a member of the American Medical Association is entitled to individual membership in the World Medical Association. Support through such memberships enables the World Medical Association to carry on its important activities. With membership comes a subscription to the *World Journal of Medicine*, which gives a view of the world scene in medicine. In support of the World Health Organization, the physician should familiarize himself with its values to the United States both as an arm of the foreign policy of our government and as a contributor to our domestic health. He can assist in developing understanding within his own community concerning the importance of the development of public health services in underdeveloped areas of the world as a barrier to the spread of communism.

Each of these organizations and both of them together give the physician a chance to be active within his own community in the interest of better world health. There is no single field in which a more fundamental job can be done in the building of a sound basis for peace than the field of health and medicine through nongovernmental and governmental action. This basis, indeed, gives physicians a singular opportunity to contribute to the future of mankind, an opportunity probably greater than enjoyed by any other profession.

University of Minnesota Medical School (14) (Dr. Diehl).

Doctor and Workingman.—Social and political movements have grown up to protect and sustain the workingman. These movements are begun as humanitarian protest against exploitation of human resources and usually with finest motivation. . . . Have these movements gone too far and have they reached a point of destructive paternalism? . . . One of the rewards of the American free enterprise system for an ambitious . . . workingman has been ready advancement from employed to employer status. Achievement of self-support, self-confidence and assumption of individual leadership and responsibility produce emotional satisfaction and moral growth. Current weight of benefit payments, governmental reports and audits, fund segregations and contributions, and constant emphasis upon a secure position with union benefits, workmen's compensation, guaranteed vacations, full pay when not working, annual wage, old age assistance and social security now blocks the free movement of the individual into new ventures. In day-to-day practice one sees numerous instances of workman frustration and retreat growing out of excesses of our social benefit systems. It can hardly be considered a political or reactionary protest to point out the stultifying effects of our constant quest for security without risk. —F. E. Rieke, M.D., Doctor and Workingman, *Northwest Medicine*, April, 1955.

SODIUM RETENTION AND EDEMA FROM PERCUTANEOUS ABSORPTION OF FLUDROCORTISONE ACETATE

Thomas B. Fitzpatrick, M.D., Ph.D., Herbert C. Griswold, M.D.
and
John H. Hicks, M.D., Portland, Ore.

The occurrence of untoward physiological effects after systemic administration of cortisone and hydrocortisone provided a stimulus for investigators to develop hydrocortisone lotions and ointments for topical application. By applying hydrocortisone topically, the anti-inflammatory effects could be utilized without the risk of sodium and water retention, edema, and other undesirable physiological changes associated with systemic administration. In the three years since the introduction of hydrocortisone products for topical application, occurrence of systemic absorption after topical application has not been reported. During the past 15 months since we began evaluating the therapeutic effects of topically applied hydrocortisone in various concentrations and vehicles, we have become suspicious of possible systemic absorption of topically applied hydrocortisone. For example, in using the simultaneous paired comparison method, it was often noted that the area receiving the placebo lotion or ointment appeared to respond almost equally to the area receiving hydrocortisone. Also, it was observed in a large series of patients receiving 1% and 2.5% hydrocortisone acetate lotion that improvement occurred in areas of dermatitis distant from the site of application.

To determine whether or not percutaneous absorption of 2.5% hydrocortisone acetate lotion occurs, two patients with generalized atopic dermatitis were hospitalized, and 100 ml. of lotion containing 2.5 gm. of hydrocortisone acetate was applied daily for seven days. Hydrocortisone compound F excretion was determined in three 24-hour urine specimens prior to application of the lotion and in daily 24-hour urine specimens during the seven day experimental period. There was no increase in the excretion of hydrocortisone during the period of application of 2.5% hydrocortisone acetate lotion in either of the patients. We therefore concluded that systemic absorption of detectable amounts of topically applied hydrocortisone acetate lotion did not occur. During the past year we have been evaluating lotions and ointments containing fludrocortisone acetate (9-*a*-fluorohydrocortisone acetate). The same curious phenomena were observed even more strikingly than with hydrocortisone; placebo treated areas and distant areas improved almost as rapidly and completely as the site of application of fludrocortisone acetate. Our earlier suspicions of systemic absorption of topically applied steroids were finally confirmed when, in October, 1954, generalized edema developed in a young woman with atopic dermatitis after topical application of 0.2% fludrocortisone acetate lotion.

The following five cases are presented as examples of increase in weight and edema following topical application of fludrocortisone acetate.

REPORT OF CASES

CASE 1.—A white female, aged 27, with chronic atopic dermatitis that had involved the arms and face was seen on this occasion because of pruritus and lichenification of the vulvar area. The patient was given 0.2% fludrocortisone acetate lotion to be applied three times daily. She started therapy on Saturday at noon and during the next 24 hours had used a total of 15 ml. in five applications. Monday morning the patient noted that her shoes pinched, her ankles had become swollen, and she also noted periorbital edema. The patient had, therefore, used 15 ml. of 0.2% fludrocortisone acetate lotion containing 30 mg. of fludrocortisone acetate during a 24 hour period. The edema disappeared within the next 48 hours following the interruption of therapy with fludrocortisone acetate lotion.

CASE 2.—A white female, aged 51, with subacute dermatitis involving only the left palm, was started on 0.2% fludrocortisone acetate lotion on Oct. 30, 1954, and was told to apply the lotion four times daily. After three days of application, the patient returned with ankle edema and noted a 4.5 lb. (2.03 kg.) gain in weight. She was unable to put on her shoes without discomfort. She was advised to continue the treatment and returned again on Nov. 16, 1954. At this time there had been a marked decrease in the ankle edema, the palmar surface had become dry, and the erythema had disappeared. She further continued the treatment, and the eruption cleared. Thus, the edema disappeared despite the continuation of the treatment. During the initial three day period the patient used 30 ml. of 0.2% fludrocortisone acetate lotion or 20 mg. of fludrocortisone acetate lotion daily.

CASE 3.—A white female, aged 33, with scattered patches of lichenified dermatitis on the sides of the neck, in the postauricular areas, and on the extensor aspects of the arms, applied daily approximately 5 ml. of 0.2% lotion (10 mg. of fludrocortisone acetate) to the areas of dermatitis on the right side and 5 mg. of 0.1% lotion (5 mg. of fludrocortisone acetate) to the areas of dermatitis on the left side. After three days of daily application of 15 mg. of fludrocortisone acetate lotion (a total of 45 mg.), the patient developed marked edema of the lower extremities, swelling of the face, and noted a weight gain of 12 lb. (5.4 kg.). The therapy was interrupted, and during the next 48 hours there was a rapid disappearance of the edema.

CASE 4.—A white female, aged 25, with generalized chronic atopic dermatitis, applied daily 5 ml. of 0.1% fludrocortisone acetate (5 mg.) to the upper half of the body and 5 ml. of 0.2% fludrocortisone acetate (10 mg.) to the left upper half of the body. The patient returned four days later after applying 15 mg. daily of fludrocortisone acetate and was found to have ankle edema, swelling of the face, and a 10 lb. (4.5 kg.) weight gain. The skin showed marked improvement, and the patient was instructed to apply the lotions only once daily. The edema gradually subsided, and one week later there had been an 8 lb. (3.6 kg.) weight loss.

From the divisions of dermatology and cardiology, University of Oregon Medical School.

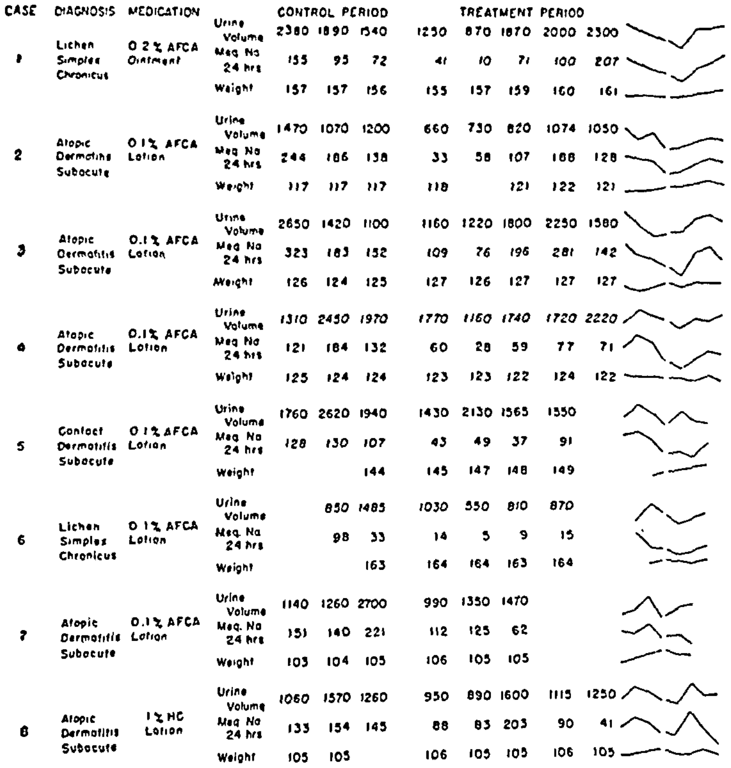
The hydrocortisone determinations were made by Dr. Peter H. Forsham, University of California Medical School, San Francisco.

The 0.1% and 0.2% fludrocortisone in absorbent ointment base (Plastibase) and 0.1% and 0.2% lotion used in this study were supplied by Dr. Harvey Blank of the Squibb Institute for Medical Research, New Brunswick, N. J. The 0.1% and 0.25% fludrocortisone lotions used in this study were supplied by Dr. Elmer Alpert of Merck and Company, Inc., Rahway, N. J.

This study was supported in part by the Squibb Institute for Medical Research, New Brunswick, N. J., the U. S. Public Health Service, and the Oregon Heart Association.

CASE 5.—A white female, aged 43, with acute contact dermatitis of the right axilla and the right lateral half of the chest and a chronic lichenified dermatitis of the dorsum of the hands, applied 7.5 ml. daily of 0.25% lotion (18.75 mg. of fludrocortisone acetate) to all areas for two days and during the next two days applied approximately 7 ml. daily of 0.1% lotion (7 mg. of fludrocortisone acetate). In four days, she had applied 51.5 mg. of fludrocortisone acetate. At the end of the treatment period (four days) she had noted a weight gain of 8 lb. (3.6 kg.). The patient was advised to apply the 0.1% fludrocortisone acetate lotion only once daily. She returned one week later, and at this time the edema had subsided but had not disappeared and she had noted a 3 lb. (1.3 kg.) weight loss.

In addition to the above patients, we have observed six patients with subacute and chronic dermatitis who have noted a weight gain of more than 5 lb. (2.3 kg.) in less than a week after starting therapy with fludrocortisone acetate lotion in 0.1%, 0.2%, and 0.25% concentrations. Furthermore, two patients with anogenital pruritus developed a weight gain of more than 5 lb. within a week, ankle edema, and puffiness of the face while using 0.2% fludrocortisone acetate in absorbent ointment base (Plastibase). All of the above patients had no evidence of cardiac disease and had not noted edema prior to therapy with fludrocortisone acetate.



CASE	DIAGNOSIS	MEDICATION		CONTROL PERIOD			TREATMENT PERIOD

Serum sodium-potassium-chloride levels and total water space and weight of patients during control period and during administration of fludrocortisone acetate. AFCA = fludrocortisone acetate.

RESULTS

In order to prove that the weight gain and edema resulted from sodium and water retention, we followed the excretion of urinary sodium in seven patients. The fludrocortisone acetate lotion or ointment was applied three times daily during the experimental period in the patients summarized in the figure. In the three patients included in the table, 0.2% fludrocortisone acetate lotion was applied every hour from 8 a. m. to 8 p. m. during the experimental period.

The following method was used. Twenty-four hour urine samples were collected from 8 a. m. to 8 p. m. The volume was measured and aliquots were saved for determinations of sodium concentration. An internal standard flame photometer technique was used. The volume times the concentration was equivalent to the total milliequivalent of sodium excreted. All sodium concentrations were based upon a standard curve obtained each day. The daily weight of patients was determined before breakfast on the same scale for each patient. Blood for sodium-potassium-chloride determination was clotted in chemically clean tubes and immediately centrifuged. The serum was promptly removed. After proper dilution, the sodium-potassium levels were determined on the flame photometer with the internal standard technique. Blood chlorides were determined by a modified Sandroy technique. Total body water levels were determined by the falling drop technique.[1] Administration of the heavy water was by the oral route.

The figure lists the daily weight changes, the 24-hour urine volume, and the total excretion of sodium in eight patients during a control period and a treatment period. The patients were on a general hospital diet with a standard intake of sodium. Water was permitted as desired. It can be seen that, without exception, there is a reduction in the sodium excretion during the first two or three days of application of the fludrocortisone acetate. In three patients there was marked reduction in the urine output, and in three patients there was a weight gain of up to 5 lb. This data would indicate that the fludrocortisone acetate contained in the lotions and ointments was absorbed through the skin and promoted retention of sodium and water.

It is of interest to note that, after the initial period of sodium and water retention, there is an increase in sodium excretion and presumably less absorption of fludrocortisone acetate. This increase in sodium excretion was coincident with improvement of the dermatitis. Although there was a variable but definite decrease in urinary sodium excretion after topical application of 1.0% hydrocortisone acetate lotion, there was no change in body weight (figure, case 8). In a group of 105 patients with dermatitis who were treated with 2.5% and 1% hydrocortisone lotion during the past 15 months, we have never observed edema.

The table depicts the serum sodium-potassium-chloride levels and total body water space, as well as weight of these patients during a control period and during administration of the various lotions. The second group of data on these three patients lists the values obtained after application of 0.2% fludrocortisone acetate lotion for three days. In general, it can be stated that there is little change in the sodium-potassium-chloride serum concentration.

The increase in total body water of the first patient in the table is equivalent to the increase in weight gain over the three day period. The data would not suggest that there is necessarily any escape of sodium into the intracellular space. This further confirms the information derived from urinary sodium excretion determinations in the preceding group of patients; namely, that salt and water are retained with an increase in the various spaces.

COMMENT

The presence of the 9-α-fluorine atom markedly increases the capacity of hydrocortisone to retain sodium.[2] The sodium and water retaining effects have limited the oral or parenteral use of fludrocortisone acetate. In a recent investigation of the antirheumatic effects of orally administered fludrocortisone acetate in doses up to 4, 6, and 8 mg. daily for 12 to 28 days, Ward and associates [2] observed a lessening of rheumatic symptoms but noted a marked retention of sodium. In one of the patients in their study, a gain in weight was noted while the patient was receiving only 2 mg. of fludrocortisone acetate daily. It is not surprising, therefore, that sodium retention and edema have been shown to occur in patients with dermatitis who are applying to the skin surface as much as 75 mg. of fludrocortisone acetate (30 ml. of 0.25% fludrocortisone acetate lotion) during a 24 hour period.

At least seven factors must be considered in estimating the amount of percutaneous absorption of fludrocortisone acetate lotion and ointment: (1) concentration of fludrocortisone acetate, (2) site of application, (3) the stage of dermatitis (acute, subacute, or chronic), (4) method of applying the ointment or lotion, (5) extent of application, (6) frequency of application, and (7) effect of vehicle.

Concentration of the Drug.—The concentration of the agent may be the most important factor in the production of sodium retention following topical application. It is estimated that in three applications daily a patient applies approximately 0.5 ml. of lotion to each 1% of the skin surface. In a patient with 40% of the skin surface involved in a dermatitis, 20 ml. of the lotion would be used in a 24 hour period. With the 0.25% fludrocortisone acetate lotion this would amount to an application of the skin surface of 50 mg. of fludrocortisone acetate and 20 mg. of fludrocortisone acetate with the 0.1% lotion. Since clinical edema has resulted after the oral ingestion of as little as 2 mg. of fludrocortisone acetate,[2] if only 1% of the applied drug were absorbed percutaneously, sodium retention and clinical edema could result. In a skin surface involved in an acute or subacute dermatitis, it is likely that much more than 1% would be absorbed percutaneously.

Site of Application.—The skin of the vulva, scrotum, and perianal areas probably has a much greater ability to absorb topically applied ointments and lotions, because of the promotion of absorption by the constant moisture in these areas. As mentioned above, two patients developed clinical edema after daily application of 0.2% fludrocortisone acetate in absorbent ointment base to the perianal area for one week.

Stage of Dermatitis.—The subjects in this series included patients with acute, weeping dermatitis; subacute dermatitis; and chronic lichenified dermatitis. It was our impression that there was a greater incidence of sodium retention and edema following topical application of fludrocortisone acetate in patients with acute dermatitis. Studies of electrolyte changes in patients applying the drug to intact skin and a larger series of patients with varying stages of dermatitis would be required to establish this belief. Other hormones (estrogens, testosterone, and progesterone) penetrate the intact skin rapidly and to a very great degree.[3] In several of our patients (e. g., case 2) the edema disappeared while the application of the lotion was continued. As the dermatitis cleared, the degree of absorption of fludrocortisone acetate appeared to decrease. Therefore, the troublesome edema that may occur in patients applying fludrocortisone acetate lotions and ointments might be considered only a temporary problem that disappears as the potent anti-inflammatory effects of the drug arrest the dermatitis with consequent decreased percutaneous absorption.

Method of Application.—Massaging or rubbing the lotion or ointment into the areas of dermatitis may enhance percutaneous absorption of fludrocortisone acetate. We have obtained the best therapeutic results with both fludrocortisone acetate and hydrocortisone acetate lotions and ointments by instructing the patient to massage a small amount into an area of skin the size of the palm of the hand. This technique of application may account in part for the increased number of patients with edema that we have observed. Several dermatologists [4] who have been evaluating fludrocortisone acetate lotions and ointments have apparently not observed edema or weight gain. Livingood,[5] however, has recently seen several patients with edema following topical application of this lotion. It is suggested that patients using fludrocortisone acetate be instructed to apply the lotion and ointment sparingly and to spread it lightly over the affected areas.

Extent of Application.—An increase in weight and edema occurred, although fludrocortisone acetate lotion was applied to less than 3% of the total skin surface

(cases 1 and 2). Fludrocortisone acetate is probably inactivated in the skin as well as the liver.[4] Thus, application of the drug to a relatively large skin surface area may actually minimize the degree of percutaneous absorption, because there is more skin surface to metabolize the steroid before absorption occurs.

Frequency of Application.—The number of applications in a 24 hour period may be a critical factor, since the rate of inactivation of the drug may be exceeded by frequent applications. The 0.2% and 0.25% lotion should not be used more than twice daily; however, application of either of these concentrations to a damaged skin or the anogenital area only once daily could result in significant absorption, if a large amount were used in one application. If 2 ml. of 0.25% lotion containing 5 mg. of fludrocortisone acetate were applied and 50% of the drug absorbed, sodium retention could result.

Effect of the Vehicle.—Our series comprises a disproportionate number of patients treated with fludrocortisone acetate lotion. The preference for the lotion vehicle is based on our repeated observation that both hydrocortisone acetate and fludrocortisone acetate in a lotion vehicle are more effective in the treatment of dermatitis. Although we have observed sodium retention and edema in two patients using 0.2% fludrocortisone acetate in absorbent ointment base, it is our impression that a greater degrees of percutaneous absorption of this drug occurs when the lotion vehicle is used. The relatively large number of patients developing sodium retention and edema that we have observed may also be related to our high index of suspicion. After we became aware of the possibility of edema from topical application of fludrocortisone acetate, all patients receiving lotion and ointment of this drug were advised to weigh themselves daily and to note signs of edema, such as pinching of the shoes, ankle swelling, puffiness of the face, and increase in waist measurement.

Finally, the potential hazard of sodium retention, hypervolemia, and edema after prolonged applications of fludrocortisone acetate in chronic recurrent dermatitis must be considered. The risk of sodium retention and a rapid increase in blood volume after topical application of this drug may be considerable in a dermatitis occurring in patients with incipient congestive heart failure, toxemia of pregnancy, nephritis, and essential hypertension. In the presence of diseases in which sodium retention may be hazardous, these lotions and ointments should be used only under careful medical supervision. Patients with a normal capacity to excrete sodium may only develop a transitory edema that disappears spontaneously as the dermatitis improves.

Decreased sodium excretion occurred after local application of 1% hydrocortisone acetate lotion, indicating a significant percutaneous absorption. As mentioned earlier, there was no increase in hydrocortisone excretion after daily application of 2.5 gm. of hydrocortisone acetate in a lotion vehicle. This may be explained by the fact that the absorbed hormone inhibits the output of corticotropin, resulting in suppression of the normal adrenal cortical secretion of hydrocortisone. Thus there is no net change in hydrocortisone excretion, despite a significant percutaneous absorption of hydrocortisone. Recent evidence of pituitary inhibition by percutaneousl absorbed hydrocortisone has been provided by Lerne and Takahashi.[6] Two patients with an abnormally hig urinary output of melanocyte-stimulating hormone applied 30 ml. of 2.5% hydrocortisone acetate lotion dail to the normal skin of the arms. After one week of th experimental period, the urinary melanocyte-stimulati hormone output decreased to a level within norm limits. After discontinuance of the local applications hydrocortisone lotion, the urinary melanocyte-stimula ing hormone output increased. Lerner and Takahas estimated that at least 3% of the applied hydrocortiso was absorbed through the normal skin. This estima was based on the amount of orally given hydrocortiso required to reduce the urinary melanocyte-stimulati hormone output to within normal limits in the same t patients. The problem of sodium retention and eder from percutaneously absorbed hydrocortisone is pro ably not important clinically, since, on a weight t weight basis, approximately 50 times more hydrocor sone than fludrocortisone must be absorbed to result the same degree of sodium retention.

SUMMARY

Evidence of sodium retention has been observed in patients after topical application of fludrocortisone a tate (9-α-fluorohydrocortisone acetate) in a lotion and ointment vehicle. Quantitative measurement of total u nary sodium excretion in seven patients with dermati who applied fludrocortisone acetate lotion and ointm revealed a decreased excretion of sodium (or a sodi retention). The principal factors that promote percuta ous absorption of fludrocortisone acetate are the conce tration of the drug, the stage of the dermatitis, and t frequency of application. In addition, percutaneous a sorption appears to occur more commonly after applic tion of fludrocortisone acetate in a lotion vehicle.

In the majority of the patients, absorption of the fludrocortisone acetate and sodium retention occurred in the early stages of treatment and decreased as the dermatitis improved even while topical applications of the drug were continued. Thus, the edema may be considered only a temporary problem that corrects itself as the dermatitis improves. However, in patients with incipient congestive heart failure, toxemia of pregnancy, essential hypertension, and nephritis the transitory sodium retention and hypervolemia may be hazardous.

Cure for Cancer.—Facts regarding the morphology of cancer are discouraging to the hope of a universal cancer cure in the near future. Many oncologists have misgivings about the recurrent statements in the lay press that cancer will be "licked" within a predictable period of time. If all cancer cells were of similar structure, and greatly different morphologically from all normal cells, we could entertain such a hope. Perhaps the most important thing we have learned in 50 years of cancer research is the complexity of the problem. This means that efforts at control and cure must be increased. . . . It looks now as if each form of cancer, and perhaps each case of cancer, may require individual treatment. . . . The victory may be won not by a single decisive battle, but by a series of successful minor engagements.—T. B. Dunn, M.D., Morphology and a Cure for Cancer, *Journal of the American Medical Women's Association*, April, 1955.

SALMONELLOSIS DUE TO SALMONELLA TYPHIMURIUM WITH EASTER CHICKS AS LIKELY SOURCE

Arnold S. Anderson, M.D., Henry Bauer, Ph.D.
and
C. B. Nelson, M.D., Minneapolis

Outbreaks of gastroenteritis in humans due to Salmo- :lla infections are common and are being increasingly entified and reported. At present there are approxi- ately 222 known Salmonella types, all of which are ithogenic to man, animals, or both. According to Feig,[1] 5% of Salmonella outbreaks reported to the U. S. Pub- : Health Service during the period 1945 to 1947 were ue to Salmonella typhimurium, which is the predominat- ig type of Salmonella. S. typhimurium is not an uncom- ion infection in chicks and other poultry.[2] It is believed iat the infection may be transmitted through the egg to ie chick and that man may become infected by eating ggs that are insufficiently heat-processed.

In Minnesota there has been an apparent increase in almonella infections recorded by the state board of ealth. Forty cases were reported in 1949, as compared) 188 cases reported in 1953. S. typhimurium was iden- fied as the etiological agent in 66 (35%) of the 188 re- orted cases. It should be pointed out that since gastro- nteritis and salmonellosis as such are poorly reported, iese cases represent, in most instances, the findings of ositive stool cultures in tests made by the division of iedical laboratories. It is therefore believed that the in- rease is more apparent than real, probably representing n increased awareness of physicians to the problem and, n part, at least, a better selection of specimens submitted o the laboratory.

It is the purpose of this report to call attention to an inusual outbreak of salmonellosis traceable to chicks hat were distributed at Easter time by food stores as a neans of publicity. Reports of similar outbreaks were ooked for in the literature, but none were found. In 953 in Hennepin County, where the outbreak under :onsideration occurred, 97 cases of salmonellosis, includ- ng 32 due to S. typhimurium, were reported by the state oard of health. From January to May, 1954, 44 cases f salmonellosis were identified in Hennepin County, 24 f which (54%) were due to S. typhimurium.

Early in May, 1954, one of us (A. S. A.) called at- ention to several cases of salmonellosis in children, with he possibility of chicks being the source of infection. The chicks under suspicion were distributed just before Easter (April 18) by two large supermarkets. With this information all cases of salmonellosis that came to the attention of the state board of health and that were sus- pected of being involved in the chick outbreak were checked through the family physician. Twelve bacterio- logically proved cases were found. In all these cases S. typhimurium was isolated from feces specimens, as indicated in table 1. The 12 patients were from 11 households; members of 10 of these households obtained chicks from one store, and a member of one household obtained them from another. Both of the stores had obtained the chicks from the same hatchery, and a total of about 1,500 chicks was distributed. The chicks had been hatched on April 15 and distributed two days later.

Investigation through cooperation of the Minnesota Live Stock Sanitary Board and the School of Veterinary Medicine revealed no trouble in the past with the hatchery. Serologic and bacteriological studies on 533 birds remaining at the hatchery, from which some of the chicks involved were hatched, showed no evidence of Salmonella infection. It is of interest to note that the chicks, while awaiting distribution at the stores, were crowded and were fed with cereal intended, but unfit, for human consumption, as the packages were broken. Specimens from the intestinal contents of five chicks from four households were examined in the medical laboratories of the Minnesota department of health; from four of these S. typhimurium was isolated and from one, S. montevideo. No attempt was made to query all persons who might have received chicks from the store or to establish the total number of persons involved; however, information obtained on the known cases revealed that 29 out of 52 persons exposed, as members of the households where illness was reported, had symptoms of gastroenteritis and probably had cases of salmonellosis. These 29 persons include the 12 who had proved cases.

CLINICAL MANIFESTATIONS

Salmonella infections are of two types, the gastrointestinal type and the septicemic type. The first type, which is quite common in pediatric practice, presents symptoms of intestinal infection. The second type is quite rare. The symptoms are those of a severe septicemia that has not localized in any one area. The complications are septic localizations of the infecting organisms. In either type of the disease the symptoms may vary from subclinical to most severe and serious. All the cases of this particular outbreak were of the gastrointestinal type and presented signs and symptoms similar to the textbook version of the disease. The case material referred to in this section will be limited to four infants and two children seen by one of us (A. S. A.). In five of the six cases the onset of the disease was from four to six days after the chicks were brought into the home, although the incubation period is usually given as a few hours to three days after ingestion of the bacteria. The symptoms came on suddenly. All the patients had fever (temperature 103 to 104 F), all had watery diarrhea, four had gross blood in the stools, and two had episodes of vomiting. Blood cell counts were done on five of the six patients;

From the St. Louis Park Medical Center (Dr. Anderson); Director, Division of Medical Laboratories (Dr. Bauer), and Chief, Section of Communicable Diseases (Dr. Nelson), Minnesota State Board of Health.

[1] Feig, M.: Diarrhea, Dysentery, Food Poisoning, and Gastroenteritis: A Study of 926 Outbreaks and 49,879 Cases Reported to the United States Public Health Service (1945-1947), Am. J. Pub. Health 40:1372-1394, 1950.

[2] Biester, H. E., and Schwarte, L. H.: Diseases of Poultry, ed. 3, Ames, Iowa, Iowa State College Press, 1952, pp. 268-273.

two had normal white blood cell counts and three had white blood cell counts between 15,000 and 20,000 per cubic millimeter, with a moderate increase in the polymorphonuclear cells. Except for marked toxic condition, tachycardia, and irregular respirations in one case, very little was revealed by physical examination. Duration of fever and severe diarrhea was from one to five days.

Since there are approximately 222 known types of Salmonella, exact diagnosis depends on the recovery of the organism from the patient. The organisms were recovered easily by stool culture during the acute phase, and this is generally true in most cases of Salmonella infection. Blood cultures were not taken. They are occasionally positive in severe cases of gastrointestinal type and almost invariably positive in the speticemic type. Determination of serum antibody titers was not done because detectable antibodies are generally not present in all cases of salmonellosis; furthermore, it would be impracticable to attempt antibody titer determinations for all possible types of Salmonella.

Only one of these six patients was hospitalized. Penicillin was given to two patients and one of the tetracyclines to three. Neither penicillin nor the tetracyclines seemed to affect the course of the disease. Chloramphenicol, 50 mg. per pound of body weight per day, in divided doses, dramatically stopped the progress of the disease in a 2½-year-old girl who became progressively more ill over a period of five days. Chloramphenicol is the antibiotic of choice and is indicated in severe cases; however, caution must be employed in using this drug because in rare instances it causes aplastic anemia. All six patients had severe diarrhea at the onset and were checked daily for dehydration and toxic condition. They were also treated by the usual dietary management and symptomatic administration of antidiarrheal drugs.

Most patients have Salmonella in their stools for s eral weeks to several months after their initial ac attack. Holt and McIntosh[3] refer to Rubenstein and co-workers "who showed that 54 percent of the patie convalescent from Salmonella infections, excrete the ganisms in the fourth week and 10 percent as late as twelfth week while 7 percent are still carriers after year. Infants are more likely to remain carriers t older children." In the past two years, one of us (A. S. has observed several children who have remained car for several months after the acute illness, but in no stance has he seen a case of Salmonella infection could be traced to one of these carriers. It has been that the use of chloramphenicol is not indicated in dren who have been carriers for less than a year. I the cases of the 1954 Hennepin County epidemic t was complete recovery. Holt and McIntosh[3] c Siligman as reporting a case fatality rate of 2.5% fants under one year of age and a rate of 1% in children. It is to be expected that chloramphenicol v lower these rates.

Concurrent with the illness of 6 patients with ga enteritis due to S. typhimurium, there were 11 members of these patients' families who had presur the same disease but were not sick enough to see a tor. Table 2 shows the age distribution of the number of sufferers from the Salmonella infection the number of those who sought medical help in th families seen by one of us (A. S. A.). Table 2 der strates that gastroenteritis caused by S. typhimuriu

ually so severe in infants less than one year of age that edical help will be sought. On the other hand, this dis- se tends to be so mild in children over the age of 2 and adults that medical help is only occasionally required. How do infants, who live in scrupulously clean cribs d seldom have anything go into their mouths that is not erilized, ingest the droppings of chickens? The answer found in the behavior of the 2 to 5-year-old. He han- les, caresses, and torments his pets and frequently ex- lores with his fingers the oral orifice of his baby sibling. may be mere chance, but we suspect it is not, that every patient under one year of age who had S. typhimurium had a sibling between the ages of 2 and 5 living in the same household.

SUMMARY

In an outbreak of salmonellosis involving at least 29 persons, with 12 of the cases proved by stool culture, the probable source was Easter chicks. This calls attention to the potential hazard of distributing chicks, ducklings, and similar small poultry for household pets.

FUTURE OF THE INTERNSHIP FROM THE STANDPOINT OF THE NONAFFILIATED HOSPITAL

Ford K. Hick, M.D., Chicago

This presentation is intended to reach into the future ather than to deal with the present years. All of us know e have to fight for house officers and find the going orse year by year. We find foreign-trained men only a artial solution. We find other ways of getting along ithout adequate house staff difficult to say the least. And o we are ourselves doing, increasingly, work formerly one by interns. To discuss these ideas I wish to state ertain premises and then to leap into the future. These remises are: 1. We do not know how to operate hospi- als without an adequate house staff. 2. The services ren- ered by interns and residents are of great value, and the timulation they supply the staff is also valuable. 3. We ust think of internships and residencies together, since nen in either status thoughtfully do day-to-day work in he care of patients.

And now to the future. As the teaching centers en- arge each one seeks a higher percentage of its own raduates as house officers. Inevitably the competition or house officers increases and the small private hospital s squeezed the hardest. Perhaps it does not matter that ne by one they give up the battle and cease to try to ualify for internship training. In the matter of pay for nterns small hospitals are criticized for trying to get in- erns by generous pay, as it is held to "imply lack of good ducation program." Are the teaching hospitals equally vorried? I believe so, and I further believe their efforts o build up strong house staffs are aimed in part at estab- ishing a future safeguard for themselves. In years gone by nany a private hospital had some advantage in supplying superior nursing service. Today, few can maintain a arge nursing staff made up of older nurses accustomed o spending much time with individual patients.

At present many a young physician wishes to have members of his own family transported even a long way to the hospital where he was trained or to a comparable one. It is implicit that a smaller hospital, or, to say it properly, one without a good house staff, cannot deliver the professional care he wishes his family to receive. A considerable number of nonmedical people do the same thing. This thinking sets the stage for an undesirable development in which the man in the street comes clearly to recognize two levels of hospital excellence. Such a development threatens to put more burdens on the "teaching hospitals" than they can bear without expansion. At the present time teaching hospitals are in the minority. They are the frosting on the cake. What will happen if everyone wishes to be cared for in them whenever illness strikes? As the teaching hospitals assume a progressively increasing importance they will be liable to lose a type of leadership they now enjoy. They will lose it because, as they supply more and more "service" to the community, they will be increasingly burdened by outside pressure. In other words, whenever the standards of the nonteaching hospitals decline so that the teaching hospitals assume the major burden of the care of the sick, then the teaching hospitals become service agencies and so must be responsive to the needs of society at large.

The teaching hospital needs to protect and to nurture its smaller neighbors for its own security. Frosting at least needs the cake. It is my hope that leadership in meeting the problem of maintaining house officers will come in part from the teaching hospitals. What means of supplying house officers to all the hospitals needing them can we imagine? First, any system of governmental medicine would find a simple solution. I have another suggestion, i. e., development of professional house officers. A hospital staff might employ young physicians to work as house officers. The attraction of a future practice in the community might get a few physicians to work, but this incentive will not supply enough help. Could not the pay be raised? Salaries of $6,000 or more might be had in some places. As the service function is to be placed foremost, salaries sufficient to attract men should not be frowned on. As these men do much for the staff it is reasonable to have staff men contribute to the fund from which their salaries are paid.

A major adjustment to professional house officers would be in our own attitudes toward them. Perhaps the increasing role of physician anesthetists sets something of a pattern for this. They work almost entirely within the hospital and on patients of other men. They are appraised by their conferees as individuals and looked upon as colleagues. True they render individually a bill for their

---

Read before the 51st Annual Congress on Medical Education and Licensure, Chicago, Feb. 7, 1955.

services, and we have no idea of permitting house officers to do that. A young physician might spend one year on such a house staff appointment and like it so well that he would wish to stay on for several years. I find no objection at all to such a practice. Youth is not an essential in a house officer. A period of one to three years could constitute a splendid background for general practice, and under certain conditions some of the specialty boards might even approve such experience as training, although that is immaterial to the possible ways of getting enough men to work as house officers. A thoughtful man so employed would learn much in such service whether board approved or not. Assistants to private physicians might appear to be a solution. In reality this requires that the physician-employer have enough volume and quality of material to interest a younger man. Common action by a hospital staff stands a better chance of success. Attempts to enlarge the general number of house officers in the nation would, I feel, be helped by dropping the requirement of internship for licensure. Almost anything that would enable the young doctor to get his license at an earlier age, in my opinion, would give him another year to follow his own career. Today he is not likely to enter private practice without considerable hospital experience.

Affiliation with a medical school is one way for a private hospital to become a teaching hospital and so to get a house staff. This arrangement may be feasible for a few hospitals located close to medical schools. There are major problems in carrying this out, however. The schools cannot permit their administrative officers and faculty to be spread out too far. Such a system can never be widespread. Among the ways hospitals have gotten along without interns is by employment of medical students as externs for night and evening work. No one is happy about this. The schools think the students pick up bad habits of observation and study and incomplete knowledge. The hospital has them only part time and for limited responsibility. The extern could make more money per hour at other work. Another radically different approach would be to greatly increase the annual number of medical graduates. Thus a larger number of physicians would assure employability of house officers paid by training or in money.

Use of procedures to make the intern's time effective will develop inevitably. Stenographic help, expansion of laboratory personnel, employment of "treatment nurses," methods of having part of the history taken by a clerk-typist, and development of forms for history taking all come to mind.

There is no way now to make the present system work to the satisfaction of all who seek house officers. To stand any chance of success any change that is proposed should be boldly planned and implemented. Our danger principally to the schools, is that we permit our lack o action to be itself an action perpetuating the present situation and imposing a progressive "service" load on the schools. I therefore urge you to look upon such matter as proposed elimination of internship for licensure and larger salaries for house officers as solutions no more radical than are demanded by the present need for adequate house staff.

SIGNIFICANCE AND IMPORTANCE OF THE INTERNSHIP FROM THE STANDPOINT OF THE SPECIALTY BOARD

David A. Boyd Jr., M.D., Rochester, Minn.

It is my assignment to discuss the significance and importance of the period known as internship from the standpoint of the medical specialty board. It is customary in allegedly literary productions for the author to deny the authenticity of either places, persons, or events contained in the account and to fix the responsibility wholly upon himself for anything that transpires after this sporting warning to the reader. In the present situation, it should be emphasized that the essayist is not speaking for the American Board of Psychiatry and Neurology, Inc., and cannot claim the following viewpoints as an official statement of policy of that board. It is even more necessary to emphasize that these statements are not authorized by the other specialty boards, and it is quite possible that different boards would have ideas in sharp and incisive disagreement with the ones expressed here. However, it is my belief that the general educational and philosophical principles underlying all medical education and all differing types of specialty training are in essential agreement regardless of the particular field of interest claimed by each specialty board. The basic educationa process must of necessity be the important common denominator underlying all types of medical educationa ventures.

It is not only illogical but intellectually impossible to defend any category that consists of only a vague generalization. The categories in the medical educational proces known as "undergraduate medical education," "internship," and "specialty training" are semantic generalizations designed to mean all things to all people. To each user the category means, as words did to Tweedledum just exactly what the user intends it to mean. Such categories, when viewed in the light of the whole educationa process, represent only crude and shifting boundaries that only mark off areas on the road that leads to competent and complete specialization. The concept of internship is only a convenient, but still a man-made, method of designating a certain part of this educational process, and, at present, it has so many sizes, shapes, and forms that it does not permit valid generalizations regarding its worth or uselessness. The disparate nature of various internships and the many varied practices throughout the country leave a commentator in the position of the frus-

trated biologist who was never able to describe one of his most interesting specimens because after each observation the organism changed into something else.

MEDICAL EDUCATIONAL PROCESS

It is far more valid and rewarding to examine the whole medical educational process leading to competency in a specialized field rather than to attempt to defend a quite artificial and vaguely defined category created for our own convenience in thinking. There is much to support the contention that the medical educational process means a progressive narrowing of the mental horizon, with ever-increasing focusing of attention and interest and with progressively increasing avoidance and neglect of ever greater areas of general knowledge and understanding. It is somewhat germane to the present discussion to note that in the premedical course the wise student takes such courses as will enable him to cope successfully with the medical curriculum, even in spite of the urging of educators for a broader knowledge of the humanities and arts. In medical school there is acceleration of this preoccupation with an ever-narrowing segment of the spectrum of knowledge. If the medical student has already decided upon a field of specialization, he may become exclusively preoccupied only with the area in which he hopes to specialize.

For example, not long ago I was in the office of the administrator of a large university psychiatric institute. The administrator answered a telephone call, and his end of the conversation was made up largely of "yes, Dean" and "I understand perfectly, Dean," finally terminating with an empurpled "well, we certainly do not condone such activities and hereafter he will be informed that he is not welcome at our conferences." When he regained composure he explained that the conversation related to a medical student who in his junior year was continuing the pattern of his sophomore year, namely, cutting classes and demonstrations whenever possible to attend the seminars and conferences held at the psychiatric hospital. He added with exasperation, "We have had a perfect rash of undergraduate medical students who are aiming only for an office practice in psychotherapy. To them the medical school curriculum and the internship are only tiresome barriers standing in their way as they attempt to progress toward their goal of an office practice in psychotherapy. Even in psychiatric residency they are not adequate because they evade all possible contact with major psychiatric disorders because these are not the type of patients that they will see in their office practice."

It should not be necessary to expound concerning the even greater increasing of preoccupation and narrowing of interest of the trainee in a specialized residency training program. In such a setting the trainee's urge to become a successful specialist, his first exuberant and enthusiastic search for applicable specialized material in his field, and the exigencies and vicissitudes of examination and certification by the specialty boards—all of these lead him to an unwavering pursuit of highly specialized knowledge and techniques with single-minded consecration toward gaining those techniques and data that appear, at least to him, as directly applicable to his intended specialty practice.

THE TOTAL INDIVIDUAL

Such an educational machine may end up by spewing forth a full-fledged specialist in his particular field of interest, but it is also likely to produce an individual who is something less than a complete physician and a complete person. Somewhere along this production line there should occur a period of reemphasis upon the nature and function of the total individual who is the patient. The program of scholastically induced, progressively more tubular vision should encompass a period in which the peripheral visual fields are trained to see in a panoramic way, even though somewhat dimly. Between the years of medical school education and the years of highly specialized training there should be a period in which the embryo physician is again made to realize that he is dealing with total personalities operating in a highly complex social, cultural, and economic environment. There is no way that this can be brought home except by having him operate as a physician in general medicine with its unparalleled opportunities to see and understand somewhat the complexities of the total human being. The specialist is less than complete, however deeply he may see into his own field of medical interest, if he is completely unable to see, even though somewhat dimly, all of the other aspects of the human being as a patient and as a member of a complicated environment. It is not important whether this period or part of the educational process is called internship, but it is important before specialization is undertaken that there occurs such a reemphasis upon the totality of the human individual as he attempts to operate within the complexities of his environment, culture, and relationships.

But it is not enough that he be taken to the mountain top and given an opportunity only to see the panorama in all of its extensiveness. It is necessary that this opportunity be provided, but only with the sharpening of vision that is given by responsibility for the management of these complex human problems under competent supervision. In medical school years he observes the patient, sometimes with considerable intellectual interest, at other times with almost casual detachment. He records the history or watches an operation, but this represents a teaching exercise in which he does not bear responsibility for the outcome in any deep emotional sense aside from doing satisfactory classroom work. He may like the patient, he may even wish him well, but the actual responsibility that should spur the intellect, sharpen the senses, and move him morally and deeply toward grasping the problem at hand, all of these are lacking in many clinical clerkships.

An anecdote may emphasize this, although it is admitted that the story is unfair and probably unkind. There is a type of psychotherapy called nondirective, in which the therapist acts as an observer and does not direct the patient's productions, usually only paraphrasing the patient's statements in a noncommittal fashion. It is stated that a depressed patient visited his therapist one day stating, "I feel awful," to which the therapist said, "You must feel pretty bad." Said the patient, "I feel bad enough to die," and the therapist replied, "You seem to be quite depressed." The patient eyed an open window and said, "I feel miserable enough to jump out of the window and here I go." Suiting action to words, he hurled himself through the open window, to the murmur of the therapist, "yep, there he goes."

The person's sense of responsibility during the years of training for a specialty usually suffers from the same type of tubular vision mentioned above. The embryo trainee feels acutely responsible for the patient's condition insofar as it relates to his own field of specialization but often with complete oblivion to the total physical and emotional needs of the patient. The total needs of the patient are too often lost as the trainee concentrates his interest and sense of responsibility only upon those areas of difficulty that lie within the confines of his own specialized interest. I was asked to see a patient in consultation some 10 days after the patient had been struck in the face with a brick. The fractures of the bones of the face had received quite adequate attention, but on the 10th day after injury the patient showed manifestations that were interpreted as restlessness, uncooperativeness, and anxiety, and psychiatric consultation was requested. The possibility of concomitant intracranial damage had not been considered, and it was quite obvious to even the psychiatric eye that the patient was dying from a subdural hematoma. As a matter of fact, he did die within the hour, but fortunately with his fractures in a state of perfect alignment.

Therefore, to the plea noted above for the panoramic vision should be added the most important leaven of responsibility for the total needs of the patient. A period intervening between the nonresponsible medical school years and the highly specialized responsibility of specialty training should be utilized for the reemphasis of the totality of the person and the ingraining of attitudes in the physician concerning his moral responsibility for not only seeing but managing, or causing to have managed, all aspects of the patient's life difficulty. This can be accomplished only if he has been trained to see them and it has been impressed upon him deeply that it is his moral obligation to see that these needs are met.

Therefore, in reviewing the educational process ending in specialty certification, it would appear to me that between medical school years and specialization, ther should be a period of experience in recognizing and man aging the total needs of the patient under supervision. I present-day internship provides this opportunity in meaningful way, the internship is a necessity and shoul be retained at all costs. If the present-day internships d not provide such an opportunity, they should be modifie at once so that these most important needs, so necessar to the development of the complete physician, are m fully and thoroughly.

102 Second Ave., S.W.

FUTURE OF THE INTERNSHIP FROM THE STANDPOINT OF THE GENERAL PRACTITIONER

William B. Hildebrand, M.D., Menasha, Wis.

From the presentation of the material and opinions presented here today by my distinguished predecessors, one receives the impression that there is no unanimity of opinion on the present status and future of the internship in the present scheme of medical education. This lack of unanimity can probably be traced to the wide divergencies of opinions concerning the purposes of an internship. Others hold that it no longer serves any purpose and should be abandoned.

FOUR VIEWPOINTS

First of all, there are those who feel that the internship is merely a preparation for the beginning of a residency, and, as such, the internship should be a straight one rather than mixed or rotating. The proponents of this theory are, of course, men who limit their practices to a very narrow special field and who feel that, in their particular realm, a rotating or a mixed internship would be a waste of time. To those who hold such views, the American Academy of General Practice, which I represent, would say that the greater knowledge that a young physician can obtain of the entire patient as an entity, the better specialist he will be. Such training cannot be obtained in a straight internship.

The second group presenting a negativistic opinion toward the internship constitutes a large group of medical educators who feel that the internship no longer serves useful purpose and should be discontinued. In 1934, 1 medical schools required an internship as a prerequisi to graduation. In 1954, only two schools had this r quirement. The change in requirement certainly ste from basic changes in the pattern of medical educatio The system of bedside teaching through clinical cler ships in the last two years of medical school is practical universal, and thus, even before graduation, the stude has become familiar with various hospital procedures a bedside techniques, formerly not obtained until the st dent had graduated. Another factor that creates dou in the minds of many medical educators as to the value an internship is the ever-increasing number of hospita approved for internships with very questionable educa tional value. To the proponents of these theories, would answer that the mere removal of the internshi from medical education would not solve anything bu would only create more problems.

The third group, and a group that I am afraid is rathe large, are those who have no concern whatsoever with the educational value of the internship and contribute nothing to the intern's education but are primarily interested in what the intern can do to help them in their private practices. For that group, the intern is expected to perform all of the chores in the hospital, including starting infusions and transfusions, catheterizations, holding retractors, watching the progress of obstetric patients,

---

President, American Academy of General Practice.

Read at the 51st Annual Congress on Medical Education and Licensure, Chicago, Feb. 7, 1955.

and so forth—all being done for the benefit of the staff and of little value to the intern once these techniques have been learned. You and I know of many doctors and many hospitals whose attitude towards interns is what and how many services can be obtained from them. With the ever-increasing number of hospitals being admitted to the internship program, I hazard a guess that many of these fall into the above category and lack even the bare essentials for an approved internship.

The fourth and last group, and one for which I speak, has always firmly advocated and supported the rotating internship as the first step in the graduate training of the young physician, especially those who plan to enter the field of general practice. Someone has said, and wisely so, that the essential purpose of the internship should be to gain practical experience for the young graduate in medical fields under competent supervision.

PLANS FOR INTERNSHIP PROGRAMS

Since there are many more internships than interns and most internships are rotating in character, the American Academy of General Practice has been much more concerned with the undergraduate programs designed to interest and prepare students for careers in general practice and with the training following internship rather than with the internship itself. However, it would seem, with 100,000 of the 160,000 practicing physicians in the country, at the present, engaged in the general practice of medicine—and, if present trends can be taken as accurate, the ratio will be maintained for some period of time—and with so much of the medical care of today therefore being dispensed by general practitioners, that the internship problem is a problem for the entire profession to solve, and it had better be accomplished with the thought of the general practitioner as paramount when a solution is reached. Some universal plan that will provide the future general practitioner with the greatest possible educational opportunities and privileges in the time allotted to him and that will provide better general medical care in the long run must thereby be worked out by all concerned.

May I then present in outline two possible plans that would seem to fit the above criteria, each somewhat different but both accomplishing the same eventual purpose. Both are predicated on the theory that two years of supervised hospital study is the absolute minimum required for the practice of medicine in any form.

Five Year Program.—The first plan is not original, but it is the plan of Dr. Roscoe L. Pullen, who is now dean of the school of medicine of the University of Missouri. He feels that the fourth year of medical school should be placed on a 12 month basis, with a month of vacation for each student staggered throughout the year, the vacation to be assigned to the needs of the hospital. All fourth year students would be placed within the teaching hospitals on a full-time basis as junior interns or some other designation appropriate for their position. The students would be rotated through the major fields of internal medicine, surgery, obstetrics, gynecology, and pediatrics. They would attend the outpatient department, the operating room, and the delivery service and in every sense follow through on the patients just as they would during the fifth or regular intern year. In view of the number of medical students now graduating, it would be possible to give them smaller patient ratios than are presently assigned to interns. By this means they would be able to attend scheduled classes once or twice daily in the subjects that are usually taught during the fourth year of medical school; namely, dermatology, ophthalmology, otolaryngology, radiology, and so forth. It would seem desirable that the students either live within or near the hospital, be subject to call just as interns now are, and accept the responsibilities thereof. These matters would naturally need to be remanded to each teaching hospital to determine whether or not it could provide housing and other facilities. If the teaching hospital could not accept all the students at once, then affiliations should be completed between the medical school and the hospitals of its community in order to assist these hospitals with intern quotas.

Then, in the fifth year, the graduate would enter the internship proper, that is, the so-called senior internship, which should be a continuation of the fourth year insofar as curriculum planning is concerned; but the fifth year intern would now be permitted to enlarge his activities and responsibilities. A curriculum would be designed that would best prepare him for his ultimate objective, whether general practice or entrance into a specialty. The internship must be regarded as an important phase of medical education, and the intern should be accorded the consideration he deserves.

Certainly, a great number of problems would immediately arise if such a plan were introduced. First of all, the medicolegal requirements of each community would need to be taken into consideration. Undoubtedly, the fourth year student could not be expected to take legal responsibility for any case involving possible litigation. Secondly, the issue of preceptorship would have to be entirely reconsidered. Thirdly, there would need to be a great change as far as the curriculum for the third and fourth years are concerned; this would then have to be integrated into the fourth and fifth years. Next, the question of assigning students to community hospitals not strongly affiliated with medical schools for part of their services would certainly have to be considered.

Of course, there are objections to such a plan as this. The responsibility for internships would be relegated more and more to the medical schools, which, however, is really happening, because the trend in postgraduate education is to the effect that medical schools should accept greater responsibility in all phases of medical education, including graduate medical education. This might mean that fewer hospitals would be approved for internships and fewer vacancies arise, for the medical schools then could effect affiliation only with the hospitals controlled or influenced by them. However, this might be a good thing, because experience has shown that probably the most effective graduate medical teaching takes place in an academic atmosphere. There would be no possible solution to the shortage of interns in outlying community hospitals under this plan. Whether the fifth year intern continued to take his training in his hospital or whether he would move to a hospital in a neighboring or distant community, as is now done in many instances, would also have to be taken into consideration.

There are many problems that would have to be worked out in this proposal, but likewise the problems would arise in any fundamental change. Dr. Pullen, however, believes—and his views are shared by many medical educators—that such a program would, as he states, enrich the educational value of the fourth year of medical education as well as the internship. It would certainly enable the graduate to increase his clinical training, and that fact alone should justify consideration of this or any other suggestions for improvement of the internship.

Two Year Internship.—The second of these proposals stems from a recommendation made by the commission on education of the American Academy of General Practice at its first meeting in 1947. This was that (1) all hospitals having internships, facilities, and training programs provide special training for doctors planning to do general practice; (2) the first year rotating internship be continued; (3) a second year internship or residency be arranged to provide the following subjects or their equivalents: (*a*) three months of general surgery and fractures; (*b*) three months of medicine, including one month of contagious diseases; (*c*) three months of obstetrics and pediatrics; (*d*) three months elective of any of the following subjects: clinical psychiatry, gynecology, laboratory, x-ray, ear, nose, and throat, or urology; (4) the second year of the internship be recognized as a residency in general practice and that a suitable certificate be presented the trainee for satisfactory completion of such training. At its 1950 annual assembly, the congress of delegates adopted the following resolution:

> Resolved, that this group is cognizant of the fact that services of interns are being dissipated in some hospitals because too much of their time is devoted to non-clinical activities and work that is not directly connected with the practice of medicine. To correct this situation, the Committee on Education of the American Academy of General Practice suggests the following. That an attempt be made to evaluate smaller hospitals which need interns and residents with the idea of establishing qualified and helpful education to these men and allow them to participate actively in the work of general practitioners throughout the nation. The committee believes that the situation would be materially improved if the Council on Medical Education and Hospitals of the A. M. A. makes an effort to improve either general practice residencies or second year internships, whichever they are called, in smaller community hospitals.

In the years following this early recommendation and this latter resolution, nothing has come upon the horizon to change the thinking behind it. Such a plan of two years' training would have some objections. It would prolong the training of men not going into general practice after the second year unless the second year intern or general practice resident would be given credit for the first year towards specialty board certification. There is certainly merit in advocating such a step, as it would place disease before the young doctor as a single discipline rather than the concept of disease in isolated tissues, cells, or organs. Certainly, complete reevaluation of hospitals acceptable for the implementation of such a program would have to be undertaken. However, such has been done before and could be done again.

Such a program would place increased teaching responsibilities on the staff of nonteaching hospitals, because such a program would require for implementation house beds now found in many community hospitals that are not engaged at the present in an internship program. There are just as many or more factors in favor of such a program. It would first of all provide hospitals with considerably more full-time medical assistance than is now available. Secondly, it would, if properly organized, provide the young doctor with worth-while experience in the practice of medicine. Third, such a plan would relieve, in part, the present shortage of interns. At the present time there are over 3,000 more approved internships than interns available. Fourth, it would, as stated above, give the future specialist a concept of an over-all picture of disease as it affects all parts of the body, a concept not now found in straight internships or residencies in specialties. Such participation of future specialists might be contingent upon whether or not specialty boards gave credit for the second year of internship or general residency, whatever it would be called. Lastly, it would result in a higher level of general medical care, for it is axiomatic that the greater amount of training given to a young graduate, the better he will be able to diagnose and manage disease in his private practice.

SUMMARY

A certain anthropologist recently in a lecture implied that an internship in the practice of medicine was similar to customs in primitive tribal behavior where the initiate, previously callow and uninformed, was introduced to the facts of life in a rather crude, if not vulgar, experience and that certain barbarities persisted in the ceremony, including humiliation and even pain for the initiate. Certainly, rather than such an appraisal of an internship, there is one that is to be greatly preferred and that is a description given by the beloved author of "Confessio Medic." He states:

> Great hospitals are something more than blocks of buildings where patients are doctored and students and nurses taught. I do believe in the spirit of the place. To me the *Genius Loci* is really there and the *Religio Discipuli,* The student's obedience to the spirit of hospital life, is a very important part of his education; or, will anyone say that the *Genius Loci* is all nonsense and that a great hospital is only a big machine? My answer is that I know what I am talking about. Sickness as Lucretius says of impending death, shows us things as they are. The mask is torn off. The facts remain. That is the spiritual method of the hospital. It makes use of sickness to show us things as they are. To a young man of good disposition, this plunge into the actual flood of lives is a fine experience.

Certainly, the internship is a natural transition into the responsibilities of residency and of practice. Let us keep it, but let us enlarge it and let us make it better.

216½ Main St.

FUTURE OF THE INTERNSHIP FROM THE STANDPOINT OF THE STATE LICENSING BOARD

Stiles D. Ezell, M.D., Albany, N. Y.

The initial reaction of the licensing boards to a prosal to abolish internships would be one of opposition. is a long-standing opinion that the internship provides period of experience involving responsibility at a level gher than the clinical clerkships, and, assuming the exrience is properly supervised, the internship represents e terminal point of interest in the education and traing of the great majority of recent medical graduates sofar as licensure requirements are concerned. Alough modern medical education may have narrowed to me extent the gap between the purposes of educational d licensing examinations, it is important to recognize at a certain differentiation still exists. Very broadly, is represents the contrast of factual knowledge and the e of judgment as applied to fitness for practice. It has en the traditional attitude of those states requiring an ternship, and perhaps the same for those not requiring that the internship experience contributes a certain deee of maturity and fitness not to be expected at the date graduation.

It might be expected that the rotating internship would me closest to meeting the requirements of the licensing ard, since its examination normally covers all major anches of medicine. As a matter of fact, there is no iformity in the present group of 27 states requiring an ternship prior to licensure. Only 11 require a rotating rvice. Residency training or actual practice may be bstituted in other states. These facts would only lend eager support for the internship as such, but there is e added fact that, according to the 1953 report of the ouncil on Medical Education, more than 99% of all merican graduates do take an internship. Hence, from e viewpoint of the medical graduate, there appears to ist a reason for serving an internship. It is doubtful if e policy of the national board in requiring an internip would influence 99% of American graduates.

If an attempt were made to explain the lack of unirmity in the various states as to the requirement of inrnship, several confusing opinions might emerge. The 1 states not requiring an internship may simply take it r granted that 99% of graduates will continue to take n internship, or that the 1% who do not is insignificant. may be their attitude that the medical schools prosly train a man to practice medicine and that an internip does not provide any appreciable educational or aining experience beyond graduation. On the other and, it may be that the requirement of internship goes ack in origin to the time when there was quite some unertainty as to the quality of education in some medical hools; or, it might be aimed at the 1% of graduates who ould not take an internship.

Perhaps the more accurate answer to the apparent ck of uniformity in the attitude of the licensing boards n the internship question is that they have not properly valuated its position in modern medical education. In terms of the broad intimations of the first World Conference on Medical Education, the internship represents the initial phase of continuation education. Thus, it serves not only as a supplement to basic undergraduate education but also as an essential introduction to postgraduate education. It may well be that the solution of the internship problem will depend upon acceptance of the concept that the internship is both an educational and an essential experience.

No licensing authorities could find fault with this idea, though some of them may be confused by the present status of the internship. The apparent inability to adjust rapid rotation to continuation education detracts from its value in much the same way the development of clinical clerkships and residency training overshadows its importance. Some of the boards may contribute to the confusion by failure to recognize the internship as an essential experience. Some may think of it only as a hospital service, and some may not differentiate between education, experience, and service.

APPRAISAL

In a more critical appraisal, the licensing boards may properly ask whether the internship is now a satisfactory period of training and experience, whether the general supervision of interns by the resident staff is an acceptable substitute for the attending staff, whether internships and residencies should not be entirely separate services, and whether the approval of internships should not be more critically approached.

Those of us in licensure who have to deal with problems involving hospital training and experience in terms of supplementary educational value consider there are two primary reasons for the present status of the internship: 1. The development of efficient clinical clerkships has moved much of the purpose and value of the internship back into the medical school. 2. A large number of approved internships do not provide a satisfactory educational or training experience. If the licensing boards are to continue their interest in maintaining high standards in licensure, it is essential that they maintain an active interest in the initial hospital experience of the recent medical graduate. Hence, they have an interest in the quality of the internship. The viewpoint of licensure is that the minimum concept of the internship demands that the examinee demonstrate a certain level of competence in definitive diagnosis and treatment.

No representative of licensure could avoid the problem of the foreign graduate as applied to hospital experience. For many of those graduates, the internship may be the first actual contact with patients. It should be for this

group both an educational and a training experience. Their first year should be restricted to hospitals capable of providing educational training, and there should be a definite fixed ratio of American graduates in every internship program accepting them. At the present time, no definite educational quality can be credited to the internship of the foreign graduate in any hospitals, except in rare instances. The one year rotating internship is grossly inadequate for the major needs of this group, in both orientation and patient management. Certainly this is a group that should not be rapidly rotated, and the ideal service would be a well-supervised rotating service of two years, unless there has been a period of formal education preceding. The internship for this group should represent a level of supervision comparable to the clinical clerkship.

SUMMARY

Licensure's only logical attitude toward the internsl is one of vigorous defense. The internship, as either educational or a training experience, represents an i portant phase of the area of medical education invol in the licensing examination. The interest of licensur hospital experience extends to the level of definitive di nosis and treatment. The problem of the foreign gradu should not be overlooked. As viewed by licensure boa one of the three major components of modern med education, namely, initial continuation education as r resented by the internship, is in urgent need of recon eration. For the large group of graduates who come fr outside the United States and Canada, the internship necessity.

FUTURE OF THE INTERNSHIP FROM THE STANDPOINT OF THE MEDICAL SCHOOL

John McK. Mitchell, M.D., Philadelphia

It has been suggested that the internship as a separate phase of medical education should be discarded and that the experience gained during this period should be divided between the clinical clerkship on one side and residency training on the other. At one time, the internship provided not only the first contact with patients but also the final step in preparation for practice. Little wonder then that it came to be regarded with high esteem. However, as the clinical clerkship was introduced into medical school teaching, it gradually evolved into training that closely simulated that which the intern had received in at least the earlier months of his service. Then, with the development of residency training programs in preparation for specialty practice, the resident began to assume some of the responsibility for the care of patients formerly assigned to the intern. Thus, the internship lost much of its earlier glory as the alpha and omega of formal clinical training.

PROBLEMS OF INTERNSHIP

It will be freely admitted by all who are familiar with the modern internship that it has many faults and that some of these faults result from pressure of the clinical clerk below and the resident above. This situation is generally considered to result in too much supervision, too little responsibility, and insufficient work with patients. In answer to these assumptions, however, we have available the results of a questionnaire on the internship submitted by an advisory committee of the Council on Medical Education and Hospitals to graduates of the 1937 and 1947 classes. Considering the latter class only, as closer to the present, the following results should be noted: 1. Eighty-eight and nine-tenths per cent thought that the presence of a residency training program in their hospital had improved the value of the internship, against 4.9% who felt that it had tracted. 2. Seventy-two and eight-tenths per cent lieved that the presence of clinical clerks improved internship, while only 1.2% considered it detrimer 3. Seven hundred eighty-eight checked lack of su vision as a major defect in their internship, as oppose 684 for lack of responsibility. 4. Seven hundred forty- thought their patient load too heavy, while only 71 c sidered it too light. 5. Lack of supervision and too he patient load stood first and second as faults, while lac responsibility and insufficient patient load stood 4th 15th respectively. This evidence indicates strongly the squeeze on the intern from clerk and resident is the sole or, indeed, the major defect in the internship is my belief that it has become the main whipping for the ills of the internship merely because it is the n obvious one.

The internship does, nevertheless, present a vex problem, as is attested by the number of committ charged with studying it and by the attention devoted t in articles and meetings. The proposal that the interns should be given up and its duties divided between clerkship and the residency would appear, at first glar to represent an easy and practical solution to these pr lems. It is my own belief that this plan is neither easy practicable, and that, on the contrary, the internship (1) a necessary and integral step in the progression fr student to practitioner, (2) now in its proper place, a (3) can actually be discarded in name only.

STEPS IN MEDICAL EDUCATION

In order that the exact place of the internship in t American plan of medical education may be clearly u derstood, a brief résumé of the successive steps in th process may be helpful. The first or premedical peri consists of general education in college, with the inclusi of certain prescribed courses necessary as forerunners medical education proper. The next step consists of medi

cal school training and is subdivided into two relatively equal periods, one devoted to the study of basic science material and the other to clinical training, generally referred to as the clinical clerkship. The third step of graduate education or hospital training is likewise subdivided into two periods, though they are usually unequal in duration, the internship and residency training. Three of these subdivisions, the clerkship, the internship, and the residency, should be examined more closely with reference to the result if the internship is discarded and merged with the other two.

The Clinical Clerkship.—The clerkship represents the first step in the application of basic science knowledge to the care of patients. It now occupies the last two years of medical school and is divided roughly as follows: (1) inpatient clerkships in medicine, surgery, obstetrics-gynecology, pediatrics, and psychiatry; (2) outpatient experience in the above services and in the various medical and surgical specialties; (3) preventive medicine and public health, often through home care and similar plans; (4) electives; (5) research; (6) clinics, conferences, and lectures to supplement the above experience and tie it in with the appropriate basic science background.

The Internship.—In one sense, the internship is merely a name for the first year of graduate or hospital training. It represents that period when the student becomes a physician, when his primary duty is responsibility for the care of the patient, when reading and attendance at conferences, clinics, lectures, and other educational experiences must ever be sacrificed to the call of the operating room, the demands of the emergency or admitting ward, and the needs of patients. While the internship is an educational experience, nevertheless, the emphasis must inevitably be placed on service to the patient, for that is the very reason for the existence of the hospital, and the intern is the servant of the hospital. The internship represents a step that must be taken and, when properly designed, merges very nicely into the next step, that of residency training.

The Residency.—A well-planned residency training program picks up where the internship ends, and, through graduated responsibility for the care of patients and the acquisition of skill in the performance of technical procedures, brings the resident to a point where he can be certified as having acquired the training and experience necessary to the practice of a given specialty.

THE PLAN TO DISCARD THE INTERNSHIP

Effect on the Clerkship.—There are vital differences between the duties and responsibilities of the clerk and the intern. As stressed above, the first duty of the intern is to the patient, and this must be so. While it is very important that the clerk should feel responsible for following every event in the progress of his patient throughout his hospital course, and in many instances he may and does miss other assignments because of this, nevertheless, if by participating in these other activities he fails to be present at some crucial moment in the patient's illness, the loss is only to the student, for he is not directly responsible for the treatment of the patient. On the contrary, the intern or his relief must be on the scene 24 hours a day, seven days a week, 52 weeks a year. It is simply impossible for anyone to fulfill this service obligation and at the same time meet the demands of medical school education, one or the other will suffer seriously; and, since the patient cannot be neglected, it is quite clear that it is the medical school work that would suffer most.

When the third year clinical clerk goes on the ward on any service, he is totally unprepared to assume the responsibilities now rightfully delegated to the intern, for his training has not brought him to this point. It becomes clear then that the student must spend his third year as an inpatient clinical clerk, in order that he may be equipped to undertake many of the responsibilities now belonging to the intern. It follows that the clerk-intern work must then be concentrated in the fourth year. In order to do this work properly, under the specifications laid down above, the student would have no time for the other activities now ordinarily assigned to the fourth year, namely: (1) a summer period that offers an opportunity for many experiences valuable to the eventual development of the physician, such as preceptorships with practicing physicians, research, junior internships in rural and specialized hospitals, industrial medicine, public health work, and special clerkships; (2) outpatient experience, which gives the student a practical introduction to a side of medical practice he does not see in the hospital (included in this is his first real training in the many medical and surgical specialties); (3) electives, which may encompass a wide variety of subjects; (4) research under the close supervision of a skilled investigator; (5) refresher and correlation work in the basic sciences; (6) home care plans; and (7) time for reading and study.

We must face squarely the practical aspects of this plan to do away with the internship as a separate phase of training. These so-called clinical clerks with intern duties would be under the residents. Human nature being what it is, the residents would unquestionably load on them the things they do not want to do themselves, and these would be the time-consuming chores offering the least medical return to the doer. One of the defects of the present internship stems from this very procedure, and it will not be cured by moving the internship into the fourth year of medical school.

In the final analysis, this plan of integration will result not in discarding the internship but in abolishing the fourth year of medical school. I, for one, am not willing to pay this price, for the gains are infinitesimal when compared with the losses. Further, having accomplished this, we would be right back where we are now so far as the internship is concerned, while we would be trying to crowd the present four years of medical school into three years. The clinical services in the hospitals would almost certainly be dissatisfied with the training of this new breed of interns and would press for more clinical training in the first two years of medical school. Even now, basic science teachers are troubled by the encroachment of clinical work on their time; to shorten it further would, in my opinion, be a grave mistake.

Effect on the Residency.—Let us assume for the moment that the proposed plan was adopted, while the fourth year in medical school was retained with certain modifications. In this case, the new graduate would enter directly on his residency duties, meaning, in the vast majority of cases, his specialty training. Is this not exactly what he does now in a straight internship, for, though called an intern, he is actually starting his specialty training. Hence, this plan to discard the internship is in reality merely a plan to do away with the rotating internship. Referring again to the questionnaire filled by graduates of the class of 1947, we find the following answers: 1. Eighty-four per cent had taken a rotating internship, against 10.9% in straight services. 2. Of those who took a rotating service, 93.5% would do so again if they had a free choice. 3. Even more significantly, of those who had straight internships, only 60% indicated that they would take the same service again, while 36% declared that they would shift to a rotating service. It is my strong conviction that the rotating internship is too valuable a portion of medical training to surrender, and that conviction is strongly supported by the above figures.

CONCLUSIONS

Therefore, it is my conclusion that the internship does have a very real place in modern medical education and that it is now where it belongs, the first year of hospital training after leaving medical school. Call it what you will—internship, first year residency, junior residency, assistant residency—it remains the first year of hospital training. However viewed, there must be a first year of such training, and so one can actually do away with the internship in name only. There may be some medical schools in which the fourth year is so weak that it could be replaced with internship work without too much loss, but these are the exception, not the rule. There may be internships in which the level of training is not as high as that received by many students during their clerkship. The solution to these problems lies not in abandoning the fourth year or the internship but in having those medical schools review and improve their senior year, while the hospitals design their internship to fit the present level of training of medical school graduates.

DOES THE INTERNSHIP HAVE A PLACE IN MODERN MEDICAL EDUCATION?

Edward H. Leveroos, M.D., Chicago

In view of the development of well-organized and effectively conducted junior and senior clerkships in the majority of medical schools throughout the country and the marked expansion of the residency program, both in medical school–connected and nonaffiliated hospitals, the concept of the internship as a separate and distinct phase in medical education is difficult to justify, except perhaps as a matter of tradition. There is little question that responsibilities and duties formerly those of the intern have been increasingly delegated, on the one hand, to medical clerks and, on the other, to residents in the university hospitals and to the resident staff in nonaffiliated institutions.

There are still some areas that have been and remain the traditional province of the internship. These include indoctrination in the less technical yet highly important human relations aspects of the practice of medicine, as well as instruction in certain techniques and procedures ordinarily taught during the internship year. Considering the time and expense involved in the education and training of a doctor and the returns of the internship year in terms of adding to his professional knowledge, or of providing medical service to the community, however, it is at least open to question whether or not such a year any longer should be required. If, in fact, the period of intern training cannot be defended in terms of adequate return to the young physician, a premise that is open to question, then the internship should be considered an anachronism and, as such, abolished. In the considered opinion of many educators, medical and nonmedical, the internship no longer serves an essential purpose, and consequently it should be integrated into medical education and training at the undergraduate and residency levels.

CONSIDERATION OF THE PROBLEM

The following points are germane to any consideration of the problem.

Clerkships.—The training and educational content of junior and senior clerkships will necessarily have to be broadened in many instances to furnish the graduate with the background that will enable him to assume greater responsibilities on completion of the undergraduate curriculum. Clerkships in a number of schools have already reached the point at which the responsibilities of the senior clerk vary little if at all from those ordinarily delegated to the intern. A further expansion of the scope of the clerkship is a necessary prerequisite to the elimination of the internship.

Licensure Requirements.—The completion of a year of internship is a requirement for licensure in a number of states. Acceptance by the examining boards of these states of a year of hospital (residency) training in lieu of the internship will be a necessary step in the elimination of the internship as such.

Residency Training.—A majority of the examining boards in the medical specialties either require or recommend a year of internship as a prerequisite to residency training. With the internship eliminated, some boards may find it necessary to increase their training requirements either by broadening the base of experience in the first year of residency or by the actual addition of another year of training in the specialty. With clinical clerkships developed to a high level, it should be possible in

Read before the 51st Annual Congress on Medical Education and Licensure, Chicago, Feb. 7, 1955.

most specialties to provide for a direct transition from undergraduate to graduate (residency) status without the need of any preliminary period of orientation. The exact course to be followed can only be determined by studying of the question as it relates to each specialty.

Hospital Appointments.—Appointments to the majority of first year internships are presently made through the National Intern Matching Plan, as sponsored by various professional and hospital groups, including the American Medical Association. The same matching procedure can be followed in making house staff appointments to first year residencies. The elimination of the internship would not then affect the present matching procedure but rather would result in a change in the plan to apply to residency or other first year house staff appointments rather than internships.

Graduate Training for General Practice.—A major objective of the internship in the past has been to provide an educational experience in preparation for the general practice of medicine. It has been the opinion of the Council on Medical Education and Hospitals, furthermore, that a minimum of two years of hospital experience is necessary for the present-day practice of medicine. A program of training designed to meet the needs of graduates planning to enter general practice will necessarily, therefore, have to be developed if the internship is eliminated. The content and scope of such a program will require thoughtful consideration if the future family doctor is to have a background of graduate education and supervised experience equal to his responsibilities.

There is some justification for considering the development of two types of residency programs for general practice: one, a period of basic residency training in such fields as medicine, pediatrics, and obstetrics; and, secondly, an advanced period of training to include general surgery and some of the surgical specialties such as operative gynecology, orthopedic surgery—particularly fractures—urology, and perhaps others. The length of these programs should be of sufficient duration to give the resident sound fundamental training in the divisions of medicine in which he plans to practice.

Military Service.—Under the present law governing military service, a physician subject to call is ordinarily deferred for the period of his intern training only. The principle of deferment for completion of a year of hospital experience can be applied with equal force to first year residencies with the elimination of the internship. With the needs of the military services for physicians trained at different levels, it might in fact simplify the procurement procedure if deferment were granted in terms of years of hospital experience rather than on an artificial division of internship and residency training.

House Staff Terminology.—For purpose of clarity, some standardization of designation for members of a hospital house staff would seem to be desirable. Such a system should be simple and rather generally applicable. One such would be:

Level	Designation
1st year	Junior resident
2nd year	Assistant resident
3rd year	Resident
4th year	Senior resident

Obviously some variations in this terminology would be necessary, particularly in those specialties in which training is ordinarily of less than three years' duration, e. g., pediatrics, in which the first year resident might properly be designated as the "assistant resident" and the second year man as "resident."

House Officerships.—At the present time there are more than 5,500 hospitals that are not approved for either internship or residency training. In addition, a number of hospitals that have been approved fail to attract a house staff. With the internship eliminated, it is evident that some hospitals now approved for intern training will not be in a position to qualify for approval at the residency level. The question arises as to what this large group of hospitals can do to provide the essential services ordinarily performed by members of the intern-resident staff. The suggestion that these hospitals appoint full-time house officers on a salary basis has been advanced. Appointments of this nature, of course, have been and are being made in a number of hospitals throughout the country. In many of these hospitals, however, a clear differentiation between service and education has not been made. Appointments are offered under the guise of providing an educational experience when, in fact, the training aspects are negligible or nonexistent.

A forthright recognition of such appointments as service assignments would, I believe, be salutary. It is probable that an appreciable number of young graduates would seek such appointments, recognizing the fact that the educational returns were incidental, if the salary levels were adequate. Thus, a young physician on completing his military service or perhaps a year or two of residency training might want to build up his financial position by taking an appointment of this nature with the thought of establishing a practice in the community or deciding on his future course. A criticism of this approach can be made in that such arrangements in effect encourage the practice of medicine by hospitals. This argument is somewhat specious, however, since a number of hospitals have been making such appointments for many years, with no evidence that they encroach on the practice of medicine in the community.

As a further safeguard, however, I would like to offer the suggestion that it might be considered advisable, if not more equitable, that the medical staff of the hospital contribute directly to an educational fund over which they, the staff, rather than the hospital, would exercise control. The resident's salaries might well be paid entirely from this fund, while the hospital would provide the resident with board, room, laundry, and the usual perquisites. Such an arrangement would recognize the fact that the medical staff is the primary beneficiary in having a house officer on duty and further, that the medical staff and not the hospital exercises primary responsibility for the house officer's work in the hospital.

There are several other methods that have been utilized in providing essential services without a house staff. They are outside the scope of this discussion, however, since they are essentially methods for assigning responsibility on same type of rotation basis to members of the active and courtesy staffs rather than to residents or house officers.

PROCESS AND EFFECTS OF CHANGE

It is axiomatic that a fundamental change of this nature involving medical education at all levels should be adopted only after thorough discussion and careful planning, with a long enough period before becoming effective to allow for an orderly adjustment by all groups concerned. A five year transitional period should be long enough to permit of a reorientation from the present status to one in which the internship has been eliminated with a minimum of disruption to present house staff programs. While the primary consideration in the adoption of this policy is the value of the internship as presently organized in terms of return to the young graduate, an important factor in its consideration should be the consequent reduction of the time spent in the formal education of the doctor. If the internship is abolished without a commensurate increase in residency training requirements in most if not all specialties, a significant savings in "man years" will have been achieved. The reduction in time spent in preparing for practice will have the effect of adding to the physician population several thousand additional doctors, the number depending upon such increases as may be made in other training requirements, particularly those of the examining boards in the medical specialties.

It can be further pointed out that the adoption of the proposed policy will mean that the majority of physicians will spend an added year in professional service at a fully or partially trained level rather than as an intern. All of these factors lend support to the position that the internship should be abolished, assuming that the basic contention is sound, i. e., the internship no longer provides sufficiently advanced educational opportunities and experience to justify its continuation as a separate and distinct phase of medical education.

535 N. Dearborn St. (10).

Venereal Disease Is Still with Us.—As the first skirmishes against syphilis appeared won, a sense of false security developed, even among physicians; and in 1950 Congress began drastic cuts in the funds necessary to sustain the essential activities of the program. . . . As a result of premature de-emphasis, 34 state health departments now consider their venereal disease funds insufficient to permit effective case-finding and to insure a continual fall in rates. Supporting their belief is the fact that during 1954, 20 states experienced a rise in reported syphilis rates and 36 a rise in gonorrhea. Preliminary evidence suggests increases in additional states during 1955. . . . The optimistic belief that penicillin alone can erase venereal diseases needs to be dispelled. Case-finding and case-holding activities must be the duty of all who undertake the responsibility of managing venereal disease. The doctor who treats cases and investigates source and contacts, or refers them to the health department, promptly contributes to better control. The doctor who treats cases but neglects source and contacts breaks a significant link in the chain of infection and does a disservice to the individuals harboring unknown disease.—A. L. Van Duser, M.D., Venereal Disease Is Still with Us, *Wisconsin Medical Journal*, May, 1955.

CLINICAL NOTES

UNILATERAL TRIPLICATION OF THE URETER

REPORT OF A PATIENT WITH THREE RENAL PELVES AND THREE URETERAL ORIFICES

Herbert B. Wright, M.D.
and
Donald J. McFarlane, M.D., Cleveland

The frequency of the recognition of anomalies of kidney and ureter has greatly increased with the diagn tic aids at the disposal of the present-day physici Unilateral triplication of the ureter is one of the l common of these anomalies. Before discussing the i dence and presenting a survey of the literature, a def tion of true triplication of the ureter is necessary. often this entity has been confused with "trifid urete and "triplicate fused ureters." In attempting to us single phrase to describe the unilateral occurrence three ureters, each connected with its own pelvis in kidney and having its own ureteral orifice in the blad we had been using the term "complete" triplication the ureter. Narath [1] correctly called our attention to fact that the words "complete triplication of urete were not descriptive of the abnormality we had in mi As an example, he stated that the term "complete" sir ureter does not necessarily connote the existence of renal pelvis nor describe the location of its orifice. argued that one may speak of duplication, triplicati or quadruplication (Campbell Begg) but none of th succinct terms define whether or not each of these ure have its own renal pelvis and its own ureteral orifice. condition that we wish to discuss is the unilateral ex ence of three ureters each with its own renal pelvis its own ureteral orifice in the bladder.

INCIDENCE

A review of the literature reveals four cases of so-cal triplication of the ureter, one each reported by Lau Henline (1931),[2] Chwalla (1935),[3] Burt, Lane, Hamilton (1941),[4] and Woodruff (1941).[5] Howe only the latter case meets our definition of the requi ments of true triplication (Narath [6]). Lane and Han ton's case comes very near to meeting the definition, in their case one of the three ureters emptied through orifice into the vulva instead of the bladder.

EMBRYOLOGY

Although there has been much divergence of opinion concerning the formation and development of the human urinary system, a final acceptance of a double but closely related origin for parenchyma and excretory apparatus has been reached and may be stated in relatively simple terms. For practical purposes the pronephros and the mesonephros may be disregarded; these exist during certain early stages in the growth of the embryo, successively performing some degree of excretory function and then degenerate upon the appearance and full development of the metanephros from which the permanent renal parenchyma are elaborated.

From the caudal segment of the primordial excretory duct (wolffian) a hollow hemispherical bulb (the ureteropelvic anlage) develops and begins to grow dorsally and then cranially. At this stage it consists of a short pedicle, the ureter, with a mushroom-shaped extremity, the future renal pelvis. Further growth is concerned with an elongation of the ureter and expansion of the pelvis with subsequent division into calices, papillary ducts, and collection tubules. Simultaneously, a parenchymatous mass is assuming form. This arises from a separate anlage, the mesochyme or renoblast. The latter accompanies the ureter in its ascent, covers the primative pelvis like a cap, and eventually produces the secretory glandular portion of the kidney. Union of the two segments results in the complete normal urinary system with kidney and ureter in their usual anatomic positions.

Numerous deviations from this characteristic behavior of the ureteric bud and the associated renoblast are possible. Ascent may be incomplete, resulting in an ectopic kidney. Horseshoe kidney is the result of failure of separation of the mesochyme of both sides. Lack of development or premature arrest of a ureteric bud will result in the absence of one kidney. The mesochyme, identified with a normally developing bud, may be deficient in greater or lesser degree and agenesis or hypoplasia then follows. There may arise two or three ureteral buds from the primary excretory duct or there may be precocious splitting of the single ureteral bud (ureter fissus).

If the extra ureter is from an accessory bud, there will be an ureteral orifice for each in the bladder. If the extra ureters are from an anlage splitting process of the ureteric bud, such a process must necessarily have occurred early and only one vesicle orifice will result.

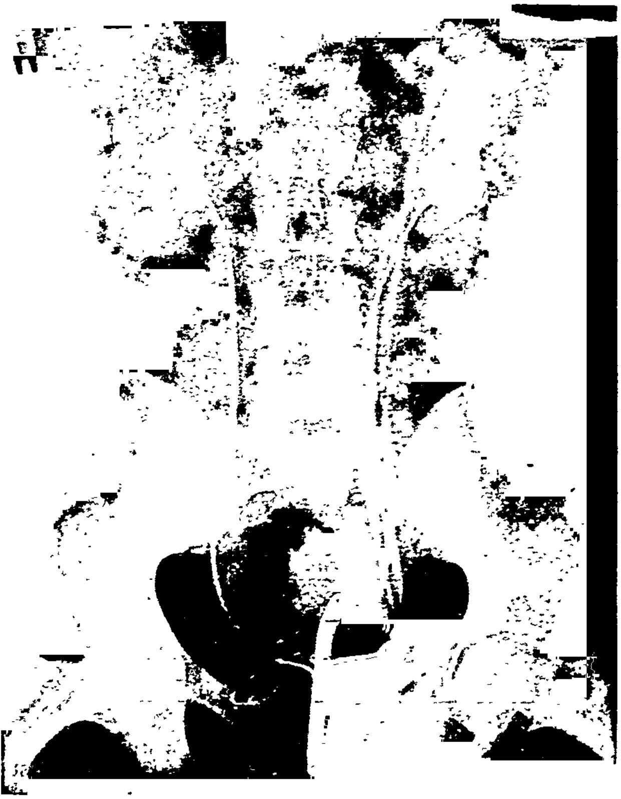
When multiple ureteral orifices exist in the bladder the following rule stated by Weigert in 1877 pertains. "The lower ureteral orifice belongs to the uppermost pelvis." The accuracy of this statement is demonstrated in both Woodruff's and our cases of triplication. Smith and Orkin [7] thought that 80% of congenital anomalies had secondary or associated pathology. Narath disagrees. He states it is illogical to pool all kinds of congenital anomalies and endeavor to thus derive a generalized percentage. Separate types must be studied and judged individually.

SIGNS, SYMPTOMS, AND TREATMENT

Patients may go through life without the knowledge that an ureteral anomaly is present unless some pathological process intervenes. Of course, pathological conditions may develop more frequently when anomalies exist. There are no signs or symptoms pathognomonic of congenital ureteral abnormality per se. The diagnosis is usually made following radiological investigation of a patient presenting symptoms of pain, frequency of urination, dysuria or hematuria, or any combination of these. The anomaly in itself requires no treatment except in event of other complicating abnormalities. One new case of true triplication of the ureter is here added to a literature containing only one other similar case.

REPORT OF A CASE

A 38-year-old married housewife entered the hospital with complaints of intermittent attacks of chills, nausea, vomiting, and mild pain in the lumbar region of the back of 10 months' duration. She had been in good health up to the time of onset when she contracted an illness diagnosed as the "flu." Subsequently she noted pain in the left lumbar region that recurred at irregular intervals, lasting for three to five days. The pain was associated with nausea, vomiting, chills, and malaise. Several weeks after the initial attack the pain subsided somewhat but not completely. Two months before admission her pain became worse, occurring every four to five days. It was described as "cramp-like" and was associated with marked sweating. The pain radiated to the lower abdomen and down the crual aspect of the leg. There was some burning on urination.



Triple left ureters.

Physical Examination.—Examination revealed an obese white female, with a temperature of 37.5 C (99.5 F), a pulse rate of 80 per minute, respirations 20, and a blood pressure of 140/88 mm. Hg. The essential physical findings were limited to the abdomen, where considerable tenderness was elicited in the costovertebral angles on both sides but more so on the left. There was tenderness along the course of the ureters anteriorly but no bladder tenderness. The urine revealed an occasional white blood cell, one to two red blood cells per high-power field, and bacteria (Micrococcus [Staphylococcus] albus). The specific gravity was 1.020, and reaction varied from acid to alkaline.

[7] Smith, E. C., and Orkin, L. A.: A Clinical and Statistical Study of 471 Congenital Anomalies of Kidney and Ureter, J. Urol. 53:11-26 (Jan.) 1945.

Repeated smears and cultures were negative for tubercle bacilli. Intravenous pyelograms and cystoscopy with retrograde pyeloureterograms (see figure), showed (1) the left kidney to have three pelves, (2) three left ureters, (3) three left ureteric orifices in the bladder, and (4) normal right kidney and ureter.

Subsequent Course.—No treatment was indicated, and the patient had no recurrence of symptoms subsequently. It was supposed that her symptoms could have been caused by a small calculus that had passed spontaneously prior to her hospital admission.

CONCLUSIONS

Triplication of ureters, each with its own pelvis and ureteral orifice, should not be confused with "trifid" or "triplicate fused ureters." One new case of unilateral triplication of the ureter, (each with its own renal pelvis and its own ureteral orifice in the bladder), is added to a literature containing only one other authenticated case.

Hanna Building (Dr. Wright).

MENINGITIS DUE TO CANICOLA FEVER

John F. Winn, D.V.M., Montgomery, Ala.
Ruell A. Stallones, M.D., Camp Pickett, Va.
and
Benjamin D. Fremming, D.V.M., Randolph Air Force Base, Texas

Because of the interest in encephalitic diseases in California a large number of serum specimens was sent in to the Virus and Rickettsial Disease Laboratory of the California State Department of Public Health during 1950. Most of these serums were from patients suspected of having one of the viral encephalitides, but a number of other diagnoses were included. Sixty-five paired serums were tested for agglutinating antibodies against Leptospira icterohaemorrhagiae, Lept. canicola, and Lept. pomona. The clinical diagnoses of these 65 were: 14 possible cases of poliomyelitis, 4 cases of Q fever, 2 of lymphocytic choriomeningitis, 2 of possible Coxsackie disease, 1 of meningitis (cause unknown), and 42 of encephalitis (cause unknown). Three of the 65 patients had antibodies against leptospiral antigens (see table).

Summary of Positive Agglutination Tests for Leptospira on 1950 Serums from California Department of Health, Virus and Rickettsial Laboratory *

			Antibodies to Leptospira Icterohaemorrhagiae								Antibodies to Leptospira Canicola								
			Acute				Convalescent				Acute				Convalescent				
Case	Age	Sex	10	100	1,000	10,000	10	100	1,000	10,000	10	100	1,000	10,000	10	100	1,000	10,000	Clinical Diagnosis
1	35	F	—	—	—	—	+	—	—	—	++++	+++	+	—	++++	++++	++	—	Lymphocytic choriomeningit
2	27	F	—	—	—	—	—	—	—	—	—	—	—	—	+	++++	+	—	Meningitis
3	11	M	—	—	—	—	—	—	—	—	—	—	—	—	++++	++++	++++	+	Poliomyelitis

* None of the serums showed agglutination antibodies against Leptospira pomona.

MATERIALS AND METHODS

The antigen was prepared from the George William Hooper Foundation cultures originally obtained from Wolff at the Institute of Tropical Hygiene in Amsterdam. Types A and B of Wiznberg strain Lept. icterohaemorrhagiae, the Hond Utrecht IV strain of Lept. canicola, and the Australis C strain of Lept. pomona were used. The culture medium was the Schuffner modification of Vervoort's medium,[1] and the antigen was prepared from the culture directly after incubation at 32 to 34 C for five to seven days. Commercial Formalin (40% formaldehyde solution) was added in an amount equivalent to 1 ml. per 100 ml. of culture and allowed to stand for four to six hours. Serial tenfold dilutions of the serum to be tested were made with saline solution, and an equal amount of antigen was added to each tube making final dilutions of 1:10, 1:100, 1:1000, and 1:10,000 or higher if indicated. The antigen serum mixtures were incubated overnight at 37 C, removed to room temperature for two hours, and read with a hand lens. After 24 hours of room temperature the specimens were read again and the readings checked with a dark field microscope. Macroscopic readings were facilitated by the use of small conical-tipped centrifuge tubes.

REPORT OF CASES

CASE 1.—A patient became ill Jan. 7, 1950. The first serum was drawn on Jan. 13 and the second on Jan. 23. Serologic tests for lymphocytic choriomeningitis, Western equine encephalitis, and St. Louis encephalitis were negative. Both acute and convalescent serums had titers of 1:128 against mumps antigen in the complement-fixation test. The slight rise in titer against Lept. canicola antigen is considered meaningful in view of the clinical diagnosis of lymphocytic choriomeningitis.

CASE 2.—A patient became ill Feb. 22, 1950. The acute serum was drawn March 2 and the convalescent March 14. These serums were tested against lymphocytic choriomeningitis, Western equine encephalitis, St. Louis encephalitis, and mumps with negative results. The rise in titer against Lept. canicola antigen leaves little doubt that this was a case of canicola fever.

CASE 3.—A third patient became ill April 16, 1950. The first serum was drawn on April 25 and the second May 9. Tests against lymphocytic choriomeningitis, Western equine encephalitis, and St. Louis encephalitis were negative. There was a titer of 1:32 against mumps antigen in both specimens. The rise in titer against Lept. canicola antigen is significant.

The experience in these three cases is in agreement with that of MacCallum and Broom of the Virus Reference Laboratory in England.[2] In 1949 they tested the serums of 130 patients with undiagnosed meningitides, abortive poliomyelitides, and similar diagnoses and found

ANSPYLORIC MUCOSAL PROLAPSE

ord H. Hermann, M.D.

rtin C. Malensek, M.D.

aham Melamed, M.D., Milwaukee

Prolapse of gastric mucosa into the duodenum has been ontroversial subject in recent years. Although some ıbt has been cast on the clinical significance and imtance of this abnormality by some authors, the mаty of writers on the subject believe gastric mucosal lapses may produce symptoms. It is not our purpose his time to consider the subject comprehensively, but consider it of interest to relate our experience in a gle case diagnosed and cured by surgery.

REPORT OF A CASE

woman, aged 39 years, entered Evangelical Deaconess spital Sept. 30, 1952, complaining of having had occasional cks of "indigestion" for several years. On the day before iission she had experienced an attack of acute epigastric pain radiated along the right costal margin and to the interpular region. During previous attacks the epigastric pain was ally dull and accompanied by nausea and vomiting. Appetite been poor for about two years. Weight loss of about 15 :0 lb. (6.8 to 9.1 kg.) during the preceding few months was rted. The patient never noticed blood in the vomitus or ls. Appendectomy had been performed 10 years previously. .950 the patient was treated at Deaconess Hospital for discoic disease. Physical examination was essentially negative ept for slight rigidity in the upper abdomen and tenderness he midepigastrium. Admission urinalysis, complete blood cell nt, sedimentation rate, and admission chest minifilm were hin normal limits. The blood Kline test was negative. Barium l (fig. 1) and enema studies, oral cholecystography, and intraous urography disclosed no essential abnormality. The patient discharged Oct. 1, 1952, unimproved and with a diagnosis ossible cholecystitis.

n Nov. 23, 1952, the patient reentered the hospital for ilar complaints, but tarry stools had been noted one week ore admission. Tenderness was present in the epigastrium and he right upper abdomen slightly below the costal margin. masses were palpable. Routine laboratory tests were again hin normal limits. The serum amylase was 120 units. Analysis the stool disclosed no alteration of fat or starch granules tent, no undigested meat fibers, and trypsin activity positive :1,000 dilution. No fever was present.

The third admission for upper abdominal distress occurred two weeks later, on Dec. 12, 1952. A few days before admission, after consuming a large meal, the patient was suddenly stricken with epigastric fulness, nausea, and repeated vomiting. The stools had been black for a day or two. The blood pressure was 116/68 mm. Hg. Generalized abdominal tenderness was present but more marked in the epigastrium and right upper quadrant. A diagnosis of psychoneurosis was made by a medical consultant. A gynecologist was unable to find any evidence of disease in the pelvis. A repeated barium enema study on Dec. 17, 1952, disclosed no change or abnormality. The red blood cell sedimentation rate; carbon dioxide combining power; serum chloride, nonprotein nitrogen, and serum potassium levels; and basal metabolic rate were within normal limits. The hemoglobin value (12.5 gm. per 100 cc.) and red blood cell count (4,100,000 per cubic millimeter) were slightly but significantly lower than on Sept. 30, 1952. A slight secondary anemia was now present for the first time.

One month later, on Jan. 15, 1953, the patient was admitted to the hospital for the fourth time. This time a diagnosis of gallbladder disease was favored. Nausea and vomiting had continued unabated since the previous admission. Pain was present in the right upper quadrant radiating to the back. No jaundice was present. The blood pressure was 120/80 mm. Hg. The red blood cell count was 4,060,000, hemoglobin, 12.5 gm. per 100 cc., and white blood cell count, 6,800. Conservative treatment was ineffective. The patient continued to lose weight and later developed a mild secondary anemia. Exploratory surgery was performed as the only alternative to the patient for possible relief of recurrent attacks of rather severe epigastric discomfort associated with at least one episode of gross bleeding. Surgical exploration on Jan. 20, 1953, disclosed no abnormality in the gallbladder, cystic and common ducts, pancreas, liver, spleen, kidneys, or small or large intestine. Palpation of the stomach revealed a soft, plum-sized, freely movable doughy mass in the antrum. This mass could be easily swayed or pushed into the duodenum. The pylorus was dilated and thickened. The surgeon recognized the condition as redundant and prolapsing gastric mucosa. Since no other cause for this patient's symptoms could be found, the surgeon performed a subtotal gastrectomy.

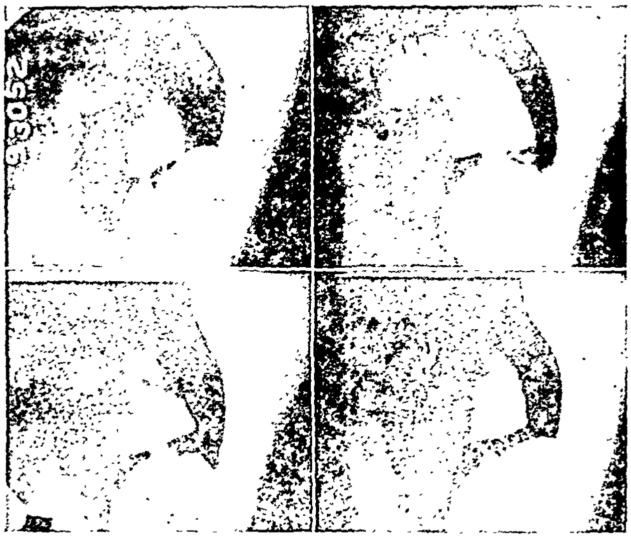

Fig. 1.—Serial barium meal studies, showing no evidence of organic disease or prolapsing gastric mucosa into duodenum. Opacified gallbladder overlies the duodenum.

The gross and microscopic pathological descriptions were as follows: "Specimen consisted of a distal stomach measuring approximately 14 cm. along the greater curvature. This has been severed just distal to the pylorus. The lumen here appears somewhat dilated but is occupied by a prolapsing mass of gastric mucosa that extends for approximately 1 cm. into the duodenum beyond the pyloric sphincter (fixed specimen). This specimen was opened along the greater curvature. This demonstrated longitudinal rugal folds in the prepyloric portion and again the prolapsing mucosal folds [fig. 2, *A* and *B*].

From the departments of surgery and radiology, Evangelical Deaconess pital.

"Sections disclose moderate hypertrophy of the pyloric sphincter and intact gastric mucosa proximal to this point. In one of the sections is very marked edema of the submucosa in the area of the pylorus and an almost polypoid elongation of the mucosa that appears to extend into the duodenum. There is no significant degree of inflammation either in the gastric or duodenal wall and there is no evidence of ulceration.

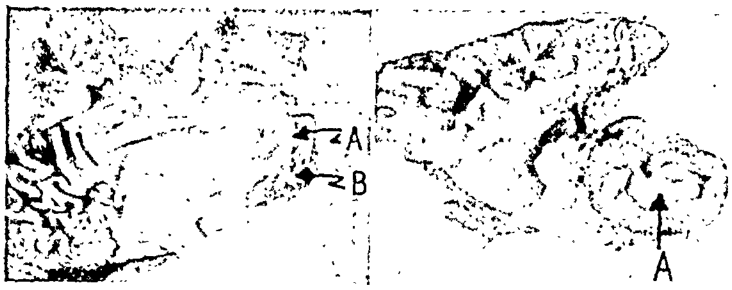

Fig. 2.—Fixed surgical specimen. *A*, redundant and prolapsing prepyloric mucosa. *B*, pyloroduodenal junction.

"Pathological diagnosis: Redundant gastric mucosa and prolapse into the duodenum."

The patient made an uneventful recovery and was discharged about 13 days after surgery. She has remained well and relieved since surgery over 30 months ago. She has gained over 10 lb. (4.5 kg.).

SUMMARY AND CONCLUSION

In a case of symptomatic transpyloric mucosal prolapse diagnosed and successfully treated by surgery, symptoms that were present for several years were relieved by subtotal gastrectomy. This case report illustrates the fact that prolapsing gastric mucosa is not always demonstrable roentgenographically. Many cases of prolapsing mucosa escape detection when the redundant membrane recedes. Such condition should always be kept in mind in all patients complaining of upper abdominal discomfort and bleeding from the gastrointestinal tract. Roentgen studies should be repeated if symptoms persist.

1821 W. Wisconsin Ave. (3) (Dr. Melamed).

COUNCIL ON PHARMACY AND CHEMISTRY

By authority of the Board of Trustees of the American Medical Association, the Council has terminated the seal-acceptance program in favor of a new program designed to render a better service to the medical profession. The following statement adopted by the Council is issued to explain the purpose, guiding principles, and operation of the new program.

R. T. Stormont, M.D., *Secretary.*

NEW PROGRAM OF OPERATION FOR EVALUATION OF DRUGS

The rate at which new drugs are being developed and marketed is increasing constantly. Often these new agents are extremely valuable additions to our therapeutic armamentarium; however, many of them are also capable of doing more harm than good if prescribed or administered in an indiscriminate fashion without full appreciation of their possible harmful effects or observance of necessary precautionary measures. A calculated risk is involved in the use of drugs that h pharmacological effects of any real significance. Th peutic agents that have a relatively narrow margi safety or a high index of serious side-effects should necessarily be condemned and discarded complet The proper use of such drugs often will save lif provide beneficial effects not obtainable with any o means of therapy. The physician has the serious sponsibility of weighing the possible harmful effects a drug against the apparent need for it in the indivi patient. Obviously, an appreciation of the valid indi tions for use as well as the known properties of a new drug is necessary in order to serve the best terests of the patient.

Many pharmaceutical firms recognize their respo bility to the medical profession and endeavor to prov such information in brochures and other literature a necessary for relatively safe and proper usage of th new drugs. Promotional literature, however, that co tains unwarranted indications for use and minimizes neglects the mention of contraindications, possible se ous side-effects, and necessary precautionary measure does not encourage the practice of rational therapeuti

There is an increasing demand from the medical pr fession in general for concise and timely reports t contain an authoritative, unbiased evaluation of n therapeutic agents. The former acceptance program the Council served a useful purpose in this regard many years; however, in this present era of rapid n developments in therapeutics, the work involved in pro essing for acceptance many different brands of a dr became cumbersome and time-consuming to the exte that physicians could no longer be provided with t type of service they desired. Consequently, termin tion of the seal-acceptance program became necess in order that the Council could embark on an expand program of operation that would be of much more i terest and value to the profession.

Under the new program drugs will be evaluated at t earliest possible opportunity in order to serve the b interests of the profession. As a rule the greatest inter in a new drug occurs at about the time it is introduced the market for general use. This is also the time wh there is the most need for an unbiased report contain information that will aid physicians in the judicious proper use of such medication. Evidence relating to new use or significant change in the status of a drug s also be evaluated and reported on as the occasion mands.

Pharmaceutical firms are encouraged to cooper with the Council by forwarding complete data or ports (published and unpublished) of all laboratory clinical investigations relating to the safety and usef ness of new drugs in order that evaluation reports may made to the profession at the earliest possible date. C operation with the Council in the selection of suita nonproprietary names for new drugs before such age are ready to be placed on the market is also encourag

The former official rules of the Council have be superseded entirely by the following description of t new program of operation.

GENERAL PURPOSE

he function of the Council on Pharmacy and Chem- is to examine and evaluate available evidence re- ig to the actions, uses, dosage, hazards, and other inent properties of drugs and to encourage rational apy by timely, informative reports to the medical ession.

pecial committees appointed by the Council also with particular matters such as research projects the toxicologic aspects of pesticides and household nicals.

NCIPLES GOVERNING THE EVALUATION OF DRUGS INCLUSION IN NEW AND NONOFFICIAL REMEDIES

he Council evaluates evidence pertaining to the ty and usefulness of medicinal agents offered or in- led for use in or on the human body for the diag- is, prevention, or treatment of disease. Reports of ie evaluations are published for the information of medical profession.

he Council considers for evaluation drugs with a le active ingredient or extracts from a single source. nbinations or mixtures containing two or more active edients may receive consideration only if it is deemed rable to present the Council's views regarding any i preparation for the information of the medical pro- ion.

n evaluating drugs the Council considers scientific ical and laboratory evidence (published or unpub- ed) submitted by manufacturers and such other re- ts as may be available. The Council also endeavors btain the opinions and advice of other experts who e in a consultant capacity. The Council does not lertake to conduct clinical and laboratory tests or eriments in evaluating drugs.

he Council may from time to time reevaluate a drug evaluate evidence relating to a new use or route of ninistration for a drug.

he views of the Council with respect to the actions, s, dosage, contraindications, hazards, limitations, and er pertinent characteristics of each evaluated drug are mitted in the form of a monograph to the Editor of E Journal of the American Medical Association for lication in the Council column. These monographs subsequently included in the Council's annual publi- on, New and Nonofficial Remedies.

f the Council's reevaluation of a drug reveals a sig- cant change in its status, such information is sub- ted to the Editor of The Journal for publication l subsequently incorporated in New and Nonofficial medies.

he Council encourages the early adoption and use of ionproprietary name for general use in prescribing, ning, and identifying each drug. The Council be- es that such names tend to diminish confusion and in the interest of the patient and physician. Each g evaluated is described by a nonproprietary name.

When the Council has knowledge that a drug is no ger available commercially or when it has been in- ded in the United States Pharmacopeia, National mulary, or New and Nonofficial Remedies for 20 rs, the monograph may be deleted from New and nofficial Remedies.

The Council does not accept, endorse, recommend, or guarantee any individual brand or preparation of a drug described in New and Nonofficial Remedies. The Council does not undertake to test or analyze samples or to review or investigate manufacturing and control procedures. The Council does not purport to ascertain whether or not any firm has complied with federal, state, or municipal laws and regulations.

SPECIFIC PROCEDURE

1. All pharmacological and clinical evidence or data in the form of published and unpublished reports on a new drug that are made available to the Council office will be referred to a number of recognized experts who will be asked to serve in a consultant capacity.

2. The views of the consultants regarding the adequacy of the evidence for the claimed uses of the new drug, as well as comments regarding such information as the limitations, contraindications, hazards, and dosage will then be transmitted to a member of the Council who will serve as a referee.

3. The referee will consider all the available evidence, as well as the views and comments of the consultants, and will make an evaluation recommendation.

4. A member of the Council staff will prepare a proposed report or monograph on the new drug based upon the referee's evaluation and recommendation.

5. The proposed monograph, the referee's recommendation, the views and comments of the various consultants, and reprints or photostats of all the available evidence will be transmitted to all the members of the Council for consideration.

6. The proposed monograph will be revised in accordance with the comments and criticisms of the members until it is satisfactory to the Council as a whole and adopted for publication in The Journal.

7. A copy of the proposed monograph will then be sent to the pharmaceutical firm or firms that supplied the evidence and data on which the Council's evaluation was based in order that they will have an opportunity for comment or criticism.

8. If there is no criticism of the proposed monograph, it will be sent to the Editor of The Journal for publication in the Council column. Any criticisms offered by the firm will receive due consideration before the proposed monograph is sent to the Editor for publication. When the monograph is published, credit will be given the firm or firms supplying the evidence or data on which the Council's evaluation of the drug is based.

9. Provision will be made for frequent publication of supplementary Council statements or reports on each new drug as evidence accumulates to justify recognition of additional valid claims for use, dosage changes, hazards, and contraindications. The same procedure for evaluation will be followed in these instances as with the initial consideration of a new drug.

10. Necessary changes or revisions based upon these supplementary statements or reports will be made in New and Nonofficial Remedies at the end of each year.

WORLD MEDICINE

Elsewhere in this issue of THE JOURNAL are a paper entitled "The Physician and World Medicine" (page 1147) and a letter to the Editor on a recent World Health Organization Assembly (page 1198). These communications indicate the growing interest in and importance of the value of considering medical problems on a world-wide basis. Each country, of course, has its own problems, but there are many aspects of the control of disease and the providing of medical care that should be viewed internationally. Sometimes the view prevailing in one country is helpful when disseminated elsewhere, and when the medical data are gathered they can be translated into terms of lessening of suffering, saving of lives, saving of money, and increasing production of goods. Such value is readily apparent to everyone.

Not so apparent at times, however, is the protection a country receives when its health professions can benefit from mistakes made elsewhere. For example, free exchange of information can not only show a country how to control, say, malaria but it can also point to the inequities of some governmentally inspired schemes that may not bring health, happiness, and freedom but instead shackles and misery. It is difficult to compare countries in different parts of the world and on the basis of such comparison devise a common plan for each compared area, and it is difficult at times to point to the weaknesses in each area. Every country has its own health and financial problems, its own social viewpoint, and its own political background. Nevertheless, there are certain fundamental principles applicable to all civilized countries. Included are those related to health, its supply and its utilization. Fundamental are freedom in the choice of a doctor by the patient and freedom in the use of modern scientific advances by the doctor. Equally fundamental is relegation of the role of government to one of assistance when necessary and not of domination or control where no need except political expediency has been demonstrated.

The World Health Organization is supported by the governments of many countries, and it has done much to provide assistance in the health field, especially in some underdeveloped areas. Its influence has been felt in widely scattered places and will be lasting in many respects. Often confused with it is the World Medical Association, which does not consist of representati
of governments but of national medical associatio
Associations from 50 countries are now members
the World Medical Association. It works closely w
the World Health Organization and with other int
national bodies interested in health. Its role in repo
ing on the activities of the International Labor Organi
tion and the International Social Security Associati
has been mentioned on previous occasions in the pa
of THE JOURNAL. To the World Medical Associati
the medical profession owes a debt of gratitude for
continual watchfulness over matters of much inte
to doctors and their patients. An excellent opportu
for doctors to see the World Medical Association in
tion will be afforded in Vienna, Austria, September
26, when the ninth General Assembly will be held.
the same time doctors and their families will be abl
visit places that have been so familiar to so many.

sociation, 345 E. 46th St., New York 17, Dr. Loui
Bauer, Secretary General. The trip will be well wo
while, but plans should be confirmed promptly.

NEW COUNCIL PROGRAMS

After months of study by the councils concerned
the Board of Trustees, a revision of the programs o
scientific councils of the Association was announce
THE JOURNAL in February (*J. A. M. A.* **157**:664 [
19] 1955). For many years these councils have prov
leadership in the evaluation of products used by
sicians and, to a lesser extent, by the public. In
evaluation programs, council seals were awarde
manufacturers and distributors of drugs, foods, dev
and cosmetics that met acceptance requirements
some instances the prominence given to the sea
acceptance program made it appear to dominate
work of the councils in the collecting, analyzing,
disseminating of medical information. Additionally,
evaluation of a multitude of individual brands, ra
than classes of products, became so time-consuming
it threatened to interfere with the broader aspects o
council programs.

For these reasons new and more effective prog
are being adopted by the scientific councils—prog
that do not require the inspection of individual prod
or the issuance of seals. The seals of the councils
the advertising emblems of THE JOURNAL and *Tod*
Health will no longer appear in Association publicati
Firms and individuals to whom the seals have
issued in the past have been notified of the new prog
and requested to eliminate the seals from collateral
vertising and promotional material by August 15, 1

There is published elsewhere in this issue of
JOURNAL (see page 1170) an announcement of the
program of the Council on Pharmacy and Chemis
Similar announcements by the Council on Foods
Nutrition, the Council on Rehabilitation, and the C
mittee on Cosmetics will follow shortly. It is our be
that the new programs will be of greater value to

fession' and the public. Released from the detail of ividual brand evaluation, the scientific councils are w free to carry out their broad objectives by methods re suited to the current needs of the profession.

Also published elsewhere in THE JOURNAL (see page 75) are the Principles of Advertising for the Publica- ns of the American Medical Association. These prin- les are essentially the same, in spirit, as those by ich products have been accepted for advertising in M. A. periodicals for many years. Thus all readers n be assured that discontinuance of the so-called seal ogram will not mean a lowering of advertising stand- ls. The special knowledge of the councils, and of other pert bodies if indicated, will be used for guidance, and product will be accepted for advertising unless the les are met.

OCTOR-DRAFT" LAW EXTENDED ROUGH PARLIAMENTARY ANEUVER

On June 28, 1955, the Congress again extended for other two years, with only slight amendment, the pro- ion of the "Doctor-Draft" law. Congress reenacted is discriminatory law after one of its staunch sup- rters was forced to confess on the floor of the House at "it cannot be supported by reason and logic." How l this occur? So that every physician may see for him- lf, there is reproduced (except for minor parliamentary aneuvers) in this issue of THE JOURNAL (see page 03), the section of the daily Congressional Record of ne 28, 1955, reporting the House action.

No responsible source on either side of this question s ever suggested that anything less than the highest ndard of medical care be provided for the armed rces. In addition, most persons would agree that there e two methods of obtaining an adequate number of operly qualified physicians to provide this care. Older ysicians can be forced into uniform by means of a dis- iminatory peace-time draft, or career military service n be made attractive enough to obtain and retain phy- ian volunteers of the caliber desired. It is in the thod, and not the end, that the American Medical As- ciation differs from the Department of Defense. The sociation insists that the doctor draft is so drastic a easure that it can be justified only when all other rea- nable means have failed. The armed forces and the ngress, on the other hand, are unwilling to relinquish ch an easy source of medical manpower and have iled to make a generally acceptable effort to provide equate incentives for career service. Nor has a satisfac- ry effort been made to utilize to the fullest the services civilian physicians in positions not requiring military atus. These are the simple facts behind the disputed ex- nsion of the doctor draft for another two years.

The supporters of a continued draft of older physi- ans take the view that the regular draft could not fur- sh a sufficient number of physicians under 35 years of e to staff the armed forces and the Public Health Service, a civilian agency. To arrive at this conclusion it is necessary to use a high estimate of requirements, a low estimate of availability, and a plan for deferring some 1,800 young physicians for at least two years, and to abandon all hope for decreasing the rate at which medical officers are leaving the military services. Further, supporters of the physician draft argue that younger physicians are not sufficiently experienced to provide a high standard of medical care; hence older and more experienced physicians must be drafted. Assuming this is a fact, the possibility of attracting experienced medical officers has been almost completely ignored. To proponents of the draft, it is either forced service or chaos. It will also be illuminating to those physicians who have served in the armed forces to learn that, according to Chairman Vinson of the House Armed Services Committee, if all medical care of dependents in the United States, and all medical care of civilian employees and veterans both in the United States and elsewhere were abolished, it would save the services of only 621 physicians!

It should be noted that the Senate coupled the doctor-draft extension to the regular Selective Service extension that had previously passed the House. Since this was an amendment to the bill, conferees were appointed by the Speaker of the House to meet with a similar group from the Senate and agree on a bill that both houses could adopt. It was the report of these conferees that was before the House. Thus different items of legislation were firmly coupled together and had to be accepted or rejected without amendment. In this parliamentary situation it was necessary, in order to get full consideration of the doctor-draft extension, to recommit the bill to conference, with instructions to strike out the doctor-draft extension. In this way it could have been brought to the floor of the House separately, in an orderly fashion, for debate and amendment on its own merits. Speaker Rayburn refused to permit such a motion to be made, so the critical vote was taken on the less desirable motion to *simply recommit* the whole measure to conference. In spite of this situation, 171 members of the House voted "Yea" on the motion to recommit (roll no. 99). These, in effect, were votes against the doctor-draft extension in its present form. On the other hand 221 congressmen voted against the motion to recommit. The bill was then speedily enacted by both Houses and signed by the President.

And so the authority to draft older physicians is extended for another two years. This is only an authorization, however, and it need not be used if the Department of Defense will make reasonable efforts to correct the basic problem. Plans should be made immediately to attract and retain experienced physicians on a voluntary basis. Medical care programs should be reviewed critically to remove obstacles to full use of civilian physicians in positions in which a uniform is not essential. The problem can be solved, but it will not solve itself. It will require an honest desire to place military medicine on a sound basis. Solution of the problem is not as easy as continued reliance on a discriminatory draft of older physicians.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

During the meeting of the American Medical Association at Atlantic City I was amazed by the number of questions asked by physicians about the workings of the parent body. It would seem from this that much educational work still needs to be done among members of the Association and that some of the material previously covered should be repeated. The question most often asked of me was, "Can anyone attend the meetings of the House of Delegates and can anyone discuss the problems presented there?" Meetings of the A. M. A. House of Delegates are open to all comers, either professionals or individuals outside of medicine. The press is always welcome to our House sessions, a fact that is confounding to our critics and sometimes stops them in their tracks. The only time this "open door" policy goes out of operation is on the extremely rare occasions when the House calls for an executive session. At those times no one is allowed to be present except the duly elected members of the House. In all the years that I served as a delegate, the executive session was seldom invoked.

Discussions on resolutions or other matters before the House are generally limited to the delegates and ex-presidents of the Association. Others who wish to speak before the House must request permission, which can be granted only by a unanimous vote; however, only delegates have the right to vote. Resolutions before the House are generally passed on by voice vote. In most instances a simple majority is all that is required to carry a measure. When the voice vote is close, the Speaker calls for a standing vote or a written ballot. The written ballot is used in cases where a proposal has generated considerable heat and extraordinary measures for accuracy in counting are demanded. It is also used when a secret ballot is desired by the House.

What other privileges are accorded a physician who is not a member of the House of Delegates? He may listen to issues debated on the floor of the House. If he has an active interest in a particular issue he can appear before the reference committee to which the matter has been assigned for hearings. Any physician member of the A. M. A. can, upon recognition, speak up at a reference committee meeting. Other guests can speak only when called upon by the committee. These meetings also are open to the press. After hearing all those who have anything to say on a given issue, whether they are members of the House or not, the reference committee goes into executive session to discuss the testimony that has been recorded by its secretary and a report is prepared for presentation to the House.

Usually the work of the House seems cut and dried because it often accepts the unanimous report of the reference committee without question; however, the House, if it wishes to, can challenge the reference committee's report. It has on many occasions mod
even reversed the recommendations of a commit
times the members of a reference committee m
a majority report and a minority report. Then
bating may become heated. The House by major
may accept either of the two reports or mak
modifications. This happened on the osteopath
at the Atlantic City session just a few weeks
many of you will remember.

So you see, any member of the A. M. A. is
to attend meetings of the House of Delegates an
voice in the proceedings. All he has to do is
reading of the resolutions, note to which commit
Speaker of the House refers them, and speak u
issues at the reference committee hearings. No
can come before the House except through the
of the officers or Board of Trustees or by res
presented by some standing comn
the House, a member of the H
an elected officer of the Ass
Where do these resolutions o

meetings resolutions are presented
resentatives of the county societ
are elected to the house of delegat
state organizations. The resolutio
sented there are also sent to r
committees where the individual
may appear to protest, agree, or o
gestions for modification. A major
in a state house may kill a resol
that level or cause it to be forwarded to the A.
House. If you favor a resolution that has been
at the state level, you still may be able to have
ject considered by the national organization by
another state delegation to present it.

I have gone into detail to explain the working
House of Delegates because so many of our
think that everything is cut and dried by the B
Trustees and that the will of the physicians of
is not considered. Nothing could be farther f
truth. I think this bears repeating again: you
come to sit in at all sessions of the House excep
tive sessions, which occur very rarely. You can
before any reference committee, whether or not
an elected member of the House. If you want
can have your say. Why not take a more active
the affairs of your Association? We need your
and your presence at meetings—not only on the
level but at your state and county sessions as well
all, *you* are the A. M. A. If you do not take a
the job we all must do, then you have only you
blame for any inadequacies.

ELMER HESS, M.D., Erie

ORGANIZATION SECTION

NCIPLES OF ADVERTISING FOR AMERICAN DICAL ASSOCIATION PUBLICATIONS

ll advertising contracts and advertising copy are subject to Principles of Advertising for American Medical Association lications. The Association reserves the right to accept or t advertising copy for any reason.

he following general rules are applicable to all advertising :

The advertiser may be required to submit data in support e usefulness of the product and the validity of the proffered ns.

Advertisements should not be deceptive or misleading.

Sweeping superlatives and unfair comparisons will not be wed. Extravagantly worded copy is subject to revision or ction.

Disparagement of a competitor's goods will not be allowed. claims for superiority must be supported by evidence accept- to the Association.

Quotations or excerpts from a published paper are accept- only if they do not distort the meaning intended by the ior. Furthermore, the mere appearance of a paper, or of ral papers, may not necessarily supply sufficient evidence to ort the proffered product or claim, and the Association in instances may request more complete data. When excerpts aken from a published paper for use in an advertisement the ciation may require the advertiser or his agent to obtain ten permission for such use from the author and if necessary, the editor or publisher of the publication in which it ars.

If testimonials or quotations appear in advertising, the lity of the claims, the expert knowledge of the person offer- the testimonial, and the probable effect of the advertisement he reader will be considered. The Association may request ence of the authenticity of the testimonial.

The Association will not accept advertisements which in judgement of the Association: (*a*) appear to violate the Prin- es of Medical Ethics; (*b*) are indecent or offensive in either or illustration; (*c*) contain attacks of a personal, racial, or ious character or appear to be contrary to the regulations laws for the prevention of discrimination; (*d*) contain claims d by any court or federal or state agency to be invalid or in ation of law.

Advertisements proposed for *Today's Health* can make rence to certain minor symptoms but not to any disease. ther words, such advertisements cannot suggest treatment disease—only temporary relief from a symptom.

The advertiser and the agency agree to protect and indem- the Association against any and all liability, loss, or expense ng from claims for libel, unfair competition, unfair trade tice, infringement of trade-marks, trade names, or patents, ations of rights of privacy and infringement of copyrights, prietary rights, and any other claims resulting from the pub- tion of advertisements by the Association.

0. The Association reserves the right to change without ce the foregoing principles.

uestions concerning advertising copy should be directed to Advertising Department of the American Medical Associa- , 535 N. Dearborn, Chicago 10.

W SERIES ON SEX EDUCATION

he Joint Committee on Health Problems in Education of the ional Education Association and the American Medical ociation have prepared the following new pamphlets on sex cation: "Learning About Love," which is for young people oth sexes about 16 to 20 years of age; and "Facts Aren't ugh," a pamphlet for adults who have any responsibility for dren that may create a need for an understanding of sex cation. These pamphlets are distributed by the two previously ed associations.

MEDICAL BOOKS FOR OVERSEAS

The U. S. Information Services in many countries have indicated a great need for books and journals in the field of medicine for libraries of medical schools and associations. Back files of medical journals and books could be usefully distributed overseas if mailed to: The U. S. Book Exchange, 1816 Half St., S. W., Washington, D. C.

The following posts have requested medical journals:

Rio de Janeiro, Brazil: The Journal of the American Medical Association.

Santiago, Chile: Technical magazines on medicine and nursing.

Ecuador: Technical periodicals in fields of medicine and dentistry.

Guatemala: Magazines on medicine.

Managua, Nicaragua: Complete set of The Journal of the American Medical Association for 1953. Sets of other medical and public health publications.

Lima, Peru: Regular shipments of periodicals of technical, professional, and scientific nature.

Vienna, Austria: Technical journals.

Berlin, Germany: Professional journals in fields of social welfare and public health.

Madrid, Spain: Regular shipments of medical periodicals.

Alexandria, Egypt: Medical journals (*American Journal of Surgery, Annals of Surgery, American Journal of Nursing, Journal of Dental Research*, etc.) 25 copies per month.

Athens, Greece: Technical and professional journals.

Bangalore, India: *Medical Clinics of North America*, The Journal of the American Medical Association.

Bombay and Hyderabad, India: Journals on health.

Teheran, Iran: Can use many copies of magazines in field of science and medicine.

Damascus, Syria: Technical and scientific journals most useful, especially public health, tuberculosis.

Taipeh, Formosa: Medical journals.

Surabaja, Indonesia: Regular shipments medical magazines for six organizations.

Beirut, Lebanon: The Journal of the American Medical Association and *Surgical, Gynecology and Obstetrics* for Governmental Hospital, Baabda. All kinds of medical journals for French Faculty of Medicine.

Buenos Aires, Argentina: Publications on cancer for Rosario Institute of Cancer.

Tegucigalpa, Honduras: Collections of medical and dental books for libraries of schools of medicine and dentistry of the National University.

THIRD STANDARD NOMENCLATURE INSTITUTE

The third series of three day classes covering the practical applications of the Standard Nomenclature of Diseases and Operations in the hospital or medical clinic will be conducted Oct. 10-12 at A. M. A. headquarters, Chicago. Included in the short course will be lectures on the theory, basic principles, and installation of the Nomenclature relating to the topographic section. Practice in coding also will be offered. Lectures on theory will be given by Adaline C. Hayden, C.R.L., associate editor of Standard Nomenclature, A. M. A., and on anatomy by Edward T. Thompson, M.D., chief of programs operations, hospital facilities, U. S. Public Health Service, Washington, D. C. Classes will be restricted to the first 100 registrants. Applications should be sent immediately to Mrs. Hayden at A. M. A. headquarters.

MEDICAL NEWS

ALABAMA

State Medical Election.—The Medical Association of the State of Alabama recently elected Dr. Frank Chenault, Decatur, president; Dr. Grady Oscar Segrest, Mobile, president-elect; Dr. S. W. Windham, Dothan, vice-president; Dr. Douglas L. Cannon, Montgomery, secretary-treasurer.

CALIFORNIA

Directory of Psychiatrists.—The Southern California Psychiatric Society is publishing a directory of psychiatrists in Southern California. Any psychiatrist in the area who has not received an information sheet is urged to request it immediately from Dr. Jerome M. Kummer, Associate Editor, Box 305, Santa Monica.

Festschrift for Dr. Bloomfield.—The May issue of the *Stanford Medical Bulletin* is a *festschrift*, dedicated to Dr. Arthur L. Bloomfield, San Francisco, emeritus professor of medicine, Stanford University School of Medicine, by more than 150 former students and colleagues. Dr. Bloomfield, who, after 26 years of teaching at Stanford, retired in 1954 as head of the department of medicine, is a former president of the California Academy of Medicine and the American Society for Clinical Investigation. During World War II he also served on the committee on medicine of the National Research Council.

Personal.—Dr. Arthur E. Smith, Los Angeles, was recently awarded an honorary doctor of science degree by Arizona State College, Tempe.——Dr. Carroll J. Bellis, Long Beach, has been declared the winner of the 1955 Mississippi Valley Medical Society essay contest for his paper, "The Management of Acute Bowel Obstruction," which he will present at the annual meeting of that society in St. Louis, Sept. 28-30.——Dr. Edward P. Luongo, Los Angeles, has been appointed associate clinical professor of medicine (industrial) at the University of California Medical School at Los Angeles. Dr. Luongo, recently elected Chairman of the Section of Preventive and Industrial Medicine and Public Health of the American Medical Association, is a director of the Industrial Medical Association.

KANSAS

Drive on Tuberculosis.—Dr. Joseph B. Stocklen, controller of tuberculosis for Cuyahoga County, was appointed by Governor Fred Hall to direct a study program in an all-out effort to eliminate tuberculosis in Kansas. Working with him will be Dr. Ralph I. Canuteson of Lawrence, director of student health service of the University of Kansas, Lawrence-Kansas City, and president of the Kansas Tuberculosis Association; Dr. George Jackson, director of institutions for the state board of social welfare; Dr. Thomas R. Hood, executive secretary of the state board of health; and Mr. W. W. Wilmore, executive secretary of the Kansas Tuberculosis Association.

University News.—Dr. Hugh L. Dwyer, clinical professor of pediatrics and of preventive medicine, and Dr. LaVerne B. Spake, clinical professor of otorhinolaryngology and chairman of the hearing and speech department, Kansas University Medical Center, Kansas City, became clinical professors emeritus July 1 in accord with the university age rule. Dr. G. O'Neil Proud, professor and chairman of the ear, nose, and throat department, has assumed chairmanship of the hearing and speech department.——Dr. Lawrence Peters joined the University of Kansas School of Medicine faculty July 1 as professor and chairman of the department of pharmacology, leaving a similar position he had held in the Tulane University of Louisiana School of Medicine, New Orleans, since 1953.

MAINE

Personal.—Dr. Lester Adams, Hebron, who has retired after 32 years as superintendent of the Western Maine Sanatorium, was honored by the townspeople of Hebron and West Minot and several hundred former patients at an open house and reception at the sanatorium. Dr. and Mrs. Adams expect to make their home in Thomaston.

New England Health Institute.—A program on the aspects of health services, entitled "Lighthouses in a Changing World," sponsored by the New England Health Institute, will be held at Colby College, Waterville, from Aug. 30 to Sept. 1. Among the topics will be local health services, changing patterns in family life, human relations in public health, teamwork in rehabilitation, tuberculosis control, accident prevention, juvenile delinquency, prevention and rehabilitation as applied to housing, prevention in dentistry, and prevention of radioactive contamination of water and aquatic life. Among the speakers will be Governor Edmund S. Muskie of Maine; Dr. Albert L. Chapman, Washington, D. C., regional medical director, U. S. Department of Health; Dr. Herman E. Hilleboe, Albany, N. Y., commissioner, New York State Department of Health; and Dr. O. Spurgeon English, head, department of psychiatry, Temple University School of Medicine, Philadelphia.

MARYLAND

Dr. Riley to Resign.—Dr. Robert H. Riley, Baltimore, chairman of the state board of health for 27 years and a member of the department since 1914, has announced his intention to resign on Jan. 1, 1956. Dr. Riley will be 76 in August, but under a law enacted by the Maryland General Assembly he was entitled to life tenure of office. It was under the Riley administration that Maryland became the first state in the nation to have full-time health services, including trained health officers, in every county.

MASSACHUSETTS

State Medical Election.—Newly elected officers of the Massachusetts Medical Society include: Dr. Conrad Wesselhoeft, Boston, president; Dr. Harold R. Kurth, Lawrence, president-elect; Dr. William A. R. Chapin, Springfield, vice-president; Dr. Robert W. Buck, Waban, secretary; Dr. Eliot Hubbard Jr., Cambridge, treasurer; and Dr. Norman A. Welch, West Roxbury, assistant treasurer.

Rehabilitation Facility for Paraplegia Patients.—Plans for an industrial rehabilitation department and neurosurgical service for the treatment of paraplegic patients have been announced by the Liberty Mutual Insurance Company and the Haynes Memorial department of the Massachusetts Memorial Hospitals, Boston, in cooperation with the Boston University School of Medicine. The new service will provide a modern rehabilitation facility for the over-all care and treatment of neurosurgical patients. To house the new department, Liberty Mutual will rebuild and reequip the east wing of Haynes Memorial Hospital to provide a unit with beds and all facilities for 26 paraplegia patients, including ambulation and exercise rooms. Dr. Donald Munro, the present chief of neurosurgical services, Boston City Hospital, who has been a consultant to Liberty Mutual since 1949, will be head of the new department.

Personal.—Dr. James Mann, director of clinical psychiatry and of research at the Boston State Hospital, has been granted a year's leave of absence beginning Sept. 1, to serve as acting director of the department of psychiatry at the Hebrew University-Hadassah Medical School in Jerusalem. Dr. Mann succeeds Dr. Milton Rosenbaum of the University of Cincinnati College of Medicine, who has been acting director of the medical school in Jerusalem for the past year. Dr. Mann plans to return to his post of clinical director at the Boston State Hospital after his

---

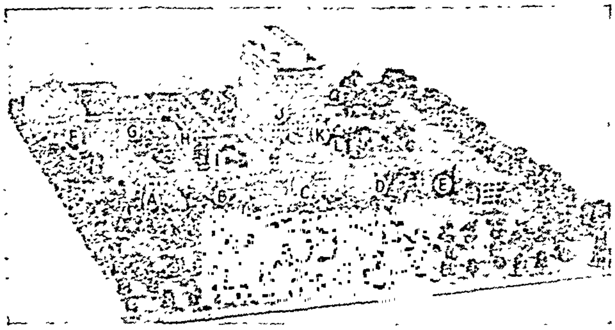
Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

year abroad.——Dr. Hugo Wolfgang Moser, Watertown, has been appointed the first research fellow of the National Multiple Sclerosis Society. The appointment supplements the national society's program of research grants, which are awarded to investigators working on specific projects.——Dr. Wyland F. Leadbetter, chief of urology at Mount Auburn Hospital, Cambridge, has been appointed associate clinical professor of surgery at Harvard Medical School and chief of the urologic service at the Massachusetts General Hospital, Boston. Dr. Leadbetter, formerly professor of urology at Tufts College Medical School, served as assistant in genitourinary surgery at the Harvard Medical School from 1946 to 1952.——The joint appointment of Dr. Howard Ulfelder, Winchester, as chief of staff of the Vincent Memorial Hospital, chief of the gynecologic service, Massachusetts General Hospital, and clinical professor of gynecology, Harvard Medical School, Boston, was recently announced.

MICHIGAN

Society News.—The Upper Peninsula Radiological Society was recently formed, and the following officers were elected: Dr. L. Grant Glickman, Menominee, president; Dr. T. Boyd Bolitho, Marquette, vice-president; and Dr. Arthur J. Gonty, Menominee, secretary. Quarterly meetings will be held.

Addition to Ford Hospital.—The 17-story building, recently added to the Henry Ford Hospital in Detroit, is designed for outpatient care and has operating rooms, staff conference rooms, an x-ray department, and laboratories. A teleradiation therapy machine to hold a cobalt bomb has been installed in a third floor room, with lead walls backed with concrete. The entire third floor is devoted to radiology, the second floor to diagnostic clinics, and the fourth floor to operating rooms. The 9 million dollar clinic building is designed to handle 4,000 outpatients a day. The hospital, which was opened on Oct. 1, 1915, with accommodations for 49 patients, now has facilities for about 700 bed patients. Associated with the hospital is the Henry Ford Hospital School of Nursing.



Henry Ford Hospital. *A*, inpatient rooms (basement being used for gastrointestinal outpatient clinic and delivery); *B*, outpatient clinic (to become inpatient rooms); *C*, administrative and outpatient clinics (part will become inpatient rooms); *D* and *E*, inpatient rooms; *F*, Clara Bryant Ford Nurses Home for student nurses of the Henry Ford Hospital School of Nursing; *G*, education building for student nurses (contains classrooms, auditorium, swimming pool, and other recreational facilities); *H*, not yet constructed; *I*, auditorium; *J*, clinic building; *K*, garage; *L*, original building of hospital (contains inpatient rooms, operating rooms, and emergency room).

MINNESOTA

Dinner for Dr. Dredge.—Dr. Homer P. Dredge was recently honored at a dinner in the state hospital in Sandstone, given under the sponsorship of the Hartley M. Robey American Legion Post. Funds contributed by Dr. Dredge's friends will be used to furnish the waiting room in the Pine County Memorial Hospital, now being erected at Sandstone, which Dr. Dredge was instrumental in promoting. Dr. Dredge has served Sandstone as health officer for over 45 years.

Society News.—The Minnesota chapter of the Arthritis and Rheumatism Foundation was recently founded in Minneapolis, with offices at 89 S. 10th St. Elected officers were Dr. Charles H. Slocumb, Rochester, president, and Drs. Macnider Wetherby and Cecil J. Watson, Minneapolis, first and second vice-presidents respectively. The foundation works for establishment of free clinics for treatment and provides for research through establishment of scholarship and laboratory grants.

Personal.—Dr. William L. Benedict, Rochester, was recently honored by his alma mater, the University of Michigan, Ann Arbor, which conferred on him the degree of doctor of laws. ——Edward A. Boyden, Ph.D., professor emeritus of anatomy, University of Minnesota Medical School, who retired as head of the department in June, 1954, attended the sixth International Congress of Anatomy in Paris, July 25-30, where he served as a member of the committee on nomenclature.——Dr. Louis A. Buie, senior consultant in the section of proctology of the Mayo Clinic, Rochester, has been appointed a consultant to the surgeon general of the U. S. Air Force. The appointment will involve inspection trips to various medical treatment facilities maintained by the Air Force and also special assignments to such specific medical problems as may arise from time to time. Dr. Buie is a member of the Judicial Council of the American Medical Association and Chairman of the Council on Constitution and Bylaws.——Dr. Henry W. Meyerding, Rochester, who retired in November, 1949, as professor of orthopedic surgery in the Mayo Foundation, has been elected an honorary member of the Turkish Surgical Association and an honorary fellow of the Philippine College of Surgeons. Dr. Meyerding recently completed an around-the-world tour by airplane, during which time he delivered lectures at various universities and surgical meetings.

NEVADA

State Medical Meeting in Reno.—The Nevada State Medical Association will hold its 52nd annual meeting and the Reno Surgical Society its sixth annual conference conjointly at the Riverside Hotel in Reno Aug. 18-20. Guest speakers will include:

Walter C. Alvarez, Chicago, The Little Strokes; Common Causes of Functional Abdominal Distress.
C. H. Hardin Branch, Salt Lake City, Immediate Management of the Psychiatric Patient; Attitudes Toward Illness.
L. Henry Garland, San Francisco, Treatment of Cancer of the Cervix; Treatment of Primary Cancer of the Breast.
Ray F. Goddard, Albuquerque, N. Mex., Respiratory Emergencies of the Newborn; Respiratory Problems in Children.
Robert A. Kimbrough Jr., Philadelphia, Bleeding During Pregnancy; Carcinoma of Uterine Fundus.
J. Lafe Ludwig, Los Angeles, Medical Legislative Problems; V. A. Problems and Current Federal Medical Legislation.
Carl V. Moore, St. Louis, Clinical Significance of Abnormal Hemoglobins; Iron Deficiency Anemias: Pathogenesis and Treatment.
Francis D. Moore, Boston, Practical Measures in Daily Care of Sick Surgical Patients; Myths and Fables in Surgical Care.
A. Neal Owens, New Orleans, Some Aspects in Treatment of Burns; Management of Cancer of the Mouth and Oral Cavity.
Robert A. Scarborough, San Francisco, Surgical Treatment of Diverticulitis of the Colon; Usefulness and Limitation of Office Procedure in Anorectal Surgery.
David A. Wood, San Francisco, Carcinoma of the Breast with Reference to Adrenalectomy in Its Management; Tumors of the Intestinal Tract with Emphasis on the Relationship of So-Called "Polyps" to Malignancy.

Among the social events will be a cocktail party Wednesday evening; a luncheon Thursday noon in the Sky Room, Hotel Mapes, where Dr. Ludwig, a member of the Committee on Legislation, American Medical Association, will be the speaker; and a cocktail party Thursday evening at Roaring Camp, Harolds Club. There will be a round-table luncheon discussion Friday noon. The banquet, Friday evening, will have as speaker, Ty Cobb.

NEW YORK

University News.—The state health department has completed arrangements with the University of Buffalo Graduate School to establish a new division of the graduate school at the Roswell Park Memorial Institute in Buffalo, which, it is anticipated, will foster graduate education in fields pertinent to cancer research, stimulate investigative programs, and make available unique research facilities.——An annual lectureship was recently inaugurated at the State University College of Medicine at New York City in Brooklyn under the auspices of the Austin Flint Society. Formerly known as the Medical History Club, the society changed its name in honor of Dr. Austin Flint, professor of practical medicine and pathology on the college's first faculty in 1860.——Dr. Isamu Suda, professor of physiology at the Kobe (Japan) Medical School, has been named visting professor of physiology at the State University of New York College of Medicine at New York City, Brooklyn, for one year, effective Sept. 1. Dr. Suda has engaged in special studies on the conditioned reflex, experimental circulatory shock, and electrical phenomena of the central nervous system.

Report on Cancer Death Rates.—According to Drs. Paul Gerhardt and Vincent Handy, Albany, director and assistant director, respectively, of the Bureau of Cancer Control, there has been a steady rise in the cancer death rate among men in upstate New York, while the cancer death rate among women has continued to drop. The continued rise in cancer deaths among men is attributed largely to the "alarming increase in lung cancer among the male population." The lung cancer death rate increased 505% in men but only 55% among women in the 20 year period from 1931-1933 to 1951-1953. The over-all male cancer death rate increased 21% in the period from 1931-1933 to 1951-1953, although the male death rate in several cancer sites declined during the same period by the following amounts: skin, 38%; stomach and duodenum, 42%; liver and biliary passages, 47%; lip, 68%; and mouth, 60%. Drs. Gerhardt and Handy report that the cancer death rate among women has been steadily declining to the point where a woman's chances of dying of this disease today are 16% lower than they were 20 years ago, due largely to a 43% decrease in the death rate from cancer of the uterus. Cancer of the breast shows a 3% increase in mortality, rising from 29.30 per 100,000 population in 1931-1933 to 30.28 in 1951-1953. The over-all cancer mortality rate for both sexes increased only 3.4% (from 166.7 deaths per 100,000 in 1945 to 172.3 per 100,000 population in 1953), but the incidence rate rose 20.3% (from 239.3 to 287.8 cases per 100,000 population) in the same period.

New York City

Research in Arteriosclerosis.—A gift of $150,000 has been made to New York Medical College, Flower and Fifth Avenue Hospitals to establish a laboratory for research in causes of and treatment for arteriosclerosis. The laboratory will be constructed on the fifth floor of the new building, contiguous with the present structure on Fifth Avenue between 105th and 106th streets, that the college is erecting as part of a 10 year expansion and development program. Dr. Harold B. Eiber has been named research director for the laboratory.

Personal.—Dr. David H. Goldstein has been promoted from associate professor to professor of the department of industrial medicine, New York University Post-Graduate Medical School. Dr. Goldstein, who is also medical director of the *New York Times* and medical director of the New York University-Bellevue Medical Center Cancer Prevention and Detection Center, has held teaching appointments with New York University College of Medicine in physiology and preventive medicine from 1936 to 1943 and since 1946.

Services for the Handicapped.—The bureau for handicapped children of the New York City Department of Health announces that the following hospital centers, to which practicing physicians may refer their patients directly, have been approved for the diagnosis, treatment, and rehabilitation of the handicapped:

Hearing centers: (1) Manhattan Eye, Ear and Throat Hospital and (2) Presbyterian Hospital.
Cleft palate centers: (1) Mount Sinai Hospital and (2) New York Hospital.
Poliomyelitis respiratory centers: (1) Goldwater Memorial Hospital and (2) Mount Sinai Hospital.
Cerebral palsy center: Bird S. Coler Memorial Hospital and Home.

Study Program in Human Health.—The New York Hospital-Cornell Medical Center has established a study program designed to investigate the manner in which man's reaction to his environment affects his health. The investigation will be concerned with cultural, social, and interpersonal aspects of human life situations. The study program, under the sponsorship of the department of medicine, is being carried out through a special medical clinic organized for the investigation of bodil disorders in which the setting of the illness, as perceived b the patient, can be studied intensively. The clinic is under th direction of Dr. Harold G. Wolff. Medical training is supe vised by Dr. Lawrence E. Hinkle Jr., Dr. Adrian M. Ostfel and the staff of attending physicians; a psychiatrist, a cultur anthropologist, and a clinical psychologist are in attendance f consultation. The clinic provides an opportunity for the trainir of undergraduate and graduate students under circumstanc that permit a broad study of individual patients and their rel tions to their total environment.

NORTH CAROLINA

Duke Center Celebrates Silver Anniversary.—Duke Universi School of Medicine and Duke Hospital, Durham, celebrat their 25th anniversary on July 21. Since the opening day, Dul Hospital has admitted 310,972 patients from all 48 states a some 14 foreign countries. Duke doctors have treated 2,864,4 ambulatory patients. The medical school has graduated 1,5 doctors and provided postgraduate training for almost 1,0 others. The school of nursing has graduated 1,000 nurses, a the medical center has trained 1,000 persons in allied medic fields. The featured visiting speaker, Dr. Edward L. Turn Chicago, Secretary, Council on Medical Education and Ho pitals, American Medical Association, had as his topic "Wh Duke University Hospital Has Meant to Medical Educati and Medical Care."

TEXAS

County Society Fund to Aid Students.—An educational tr fund, said to be the first in the nation established by a coun society, has been created by El Paso County Medical Socie to provide financial assistance to needy and qualified medic students. Any medical student from El Paso County who attending an accredited medical school in North America m apply to the fund for a loan by writing the El Paso Coun Medical Society's educational committee, which is compos of Dr. Maurice P. Spearman, chairman, Dr. Louis W. Brec and Dr. Russell L. Deter. Selection will be determined by t student's financial need and ability. The fund, which has a lif time of 25 years, is supported by annual assessments of membe of the El Paso County Medical Society. The society will acce bequests but will not engage in solicitation.

VERMONT

Seminars on Heart Disease.—The Vermont Heart Associatio in cooperation with the University of Vermont College Medicine, Burlington, will sponsor a seminar on heart disea by Dr. Wilhelm Raab, head of the cardiovascular research un University of Vermont, at the Bishop DeGoesbriand Hospit Sept. 14-15. A seminar on the electrocardiographic diagnosis auricular and ventricular hypertrophy and strain will be giv by Dr. Eugene Lepeschkin, associate professor of experiment medicine, and Dr. Borys Surawicz, instructor of medicine a research associate in experimental medicine at the Universi of Vermont, Sept. 16-17. Dr. Robert P. Grant of the Nation Heart Institute in Bethesda, Md., and Dr. E. Cabrera of t National Institute of Cardiology in Mexico City will be the gue speakers. For information concerning the seminars write Drs. Raab or Lepeschkin.

WASHINGTON

Society News.—On May 21 the Washington State Society Allergy was formally organized, and the following officers wer elected: president, Dr. Lester W. Mittelstaedt, Seattle; vic president, Dr. Robert A. Stier, Spokane; secretary-treasurer, D Lois Frayser, Seattle; members of the council, Drs. Howard Hull, Yakima, James E. Stroh, Seattle, Leslie E. Hildebran Wenatchee, and Alexander R. Altose, Seattle. The next meetin will be held in Seattle in September at the time of the meetin of the Washington State Medical Association. Any physicia applying allergy to his practice is eligible as an associate membe and may apply to the secretary, Dr. Lois Frayser, 1125 Medica Dental Bldg., Seattle.

GENERAL

Bacteriologists to Establish Certifying Boards.—At its 55th annual convention in New York May 8-12, the Society of American Bacteriologists initiated plans for the creation of an organization that will be empowered to set up certifying boards and also to engage in other activities designed to raise the standards of performance and to enhance the prestige of microbiologists.

Hospital Publication Announces Changes.—According to Dr. Edwin L. Crosby, Chicago, director of the American Hospital Association, *Hospitals*, the journal of the association, will be published twice monthly, beginning Jan. 1, 1956. The editorial staff is being expanded. Subscription and advertising rates are being increased to meet higher publishing costs, increased postal rates, and increased staffing costs.

Research on Schizophrenia.—Grants totaling $71,500 for 17 projects involved in research on schizophrenia were recently announced by F. Barry Ryan Jr., president of the National Association for Mental Health. The grants were made from a $75,000 fund provided by the Supreme Council, 33rd Degree, Scottish Rite, Northern Masonic Jurisdiction, to the National Association for Mental Health. In the last 21 years the fund has given the association more than a million dollars for research projects active in tracing down information about schizophrenia. The fund's program is set forth in a brochure, "Light for Clouded Minds," prepared by Lester Grant with the technical assistance of Dr. William Malamud, Boston, medical director of research for the Scottish Rite, and in a report, "The Scottish Rite Medical Research Program," by Dr. Malamud.

Sanitary Engineering Certification Board.—At its meeting in St. Louis in June, the board of direction of the American Society of Civil Engineers approved a proposed plan for establishing a national board of certification for sanitary engineers. The certifying agency, which will be housed in the headquarters of the American Society of Civil Engineers at New York, will be operated jointly with other professional organizations, including the American Public Health Association, interested in sanitary engineering professional development. The certifying operation, which will be similar to those already used by the medical profession for recognizing specialized competencies, is the first national certifying device ever adopted by the engineering profession. The establishment of the sanitary engineering board is the outcome of more than three years of organizational efforts toward this end.

Inter-American Scholarships.—The Inter-American Foundation for Postgraduate Medical Education (342 Madison Ave., New York) announces fellowship awards totaling $11,400 to seven physicians from Argentina, Chile, Peru, and Mexico for advanced medical training in the United States. The funds were provided through a grant from the Gustavus and Louise Pfeiffer Research Foundation. The Inter-American Foundation, established "to help improve medical education in South American and Latin American countries and to promote friendly inter-American relationships" and supported by contributions from drug companies, general industry, and foundations, has awarded 20 fellowships and supplemental grants in the past two years. Dr. Alberto Chattas, Cordoba, Argentina, is executive director; Dr. George M. Guest, Cincinnati, is president; and Mr. E. R. Leibert, New York City, is executive secretary.

Multiple Sclerosis Heredity Study.—According to the National Multiple Sclerosis Society, which is conducting a nationwide search for identical twins, one or both of whom suffer from multiple sclerosis (THE JOURNAL, July 24, 1954, page 1174; Sept. 18, 1954, page 262), there are 300 to 400 such sets in the United States. This conclusion was reached through studies by Dr. Leonard T. Kurland, chairman of the committee on epidemiology of the society (270 Park Ave., New York). Dr. Kurland's figures were arrived at following the location of 33 sets of twins, one of each pair having multiple sclerosis. The search was initiated in an effort to aid scientists at the University of Illinois under the direction of Dr. Roland P. Mackay, Chicago, in their investigation of the possible causes of multiple sclerosis. The society is issuing another appeal to locate the approximately 350 "missing" sets of twins. Persons who know of twins either identical or fraternal who have this disease are urged to communicate with Ntinos Myrianthopoulos, the Dight Institute for Human Genetics, University of Minnesota, Minneapolis.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States and its territories and possessions in the weeks ended as indicated:

Pediatric Residency Fellowships.—The American Academy of Pediatrics will grant 12 or more fellowships for pediatric residents for a period of six months to one year. These fellowships, made possible by a grant from Mead Johnson & Company, have been created to enable young physicians in financial need to complete their pediatric training. The fellowships, which will be granted as of July 1, 1956, carry a stipend of $500 to $1,000, depending on the need and the length of time required to complete training. Deadline for receipt of applications will be March 1, 1956. Requirements for the awards are: (1) a letter from the chief of service indicating that the proposed individual has completed, or will have completed by July 1, 1956, one year of pediatric training credited by the American Board of Pediatrics; that the resident has performed his work ably; and that there is real need for financial assistance; (2) a letter from the resident requesting the fellowship, stating that he intends to enter pediatric private practice at the conclusion of his second year of training. Those interested in applying may correspond with the American Academy of Pediatrics, 610 Church St., Evanston, Ill.

Meeting of National Medical Association.—The National Medical Association will hold its 60th annual convention at the Hotel Alexandria, Los Angeles, Aug. 8-11, under the presidency of Dr. Matthew Walker, Nashville, Tenn. The sessions will open at 10 a. m. Monday with a symposium on peptic ulcer, in which Dr. William P. Longmire Jr., Los Angeles, will discuss the surgical approach and Dr. Ross Golden, New York, will talk on radiology in peptic ulcer. The symposium will be followed by "Preventive Aspects of Chronic Disease" by Dr. Arnold B. Kurlander, director, Chronic Disease Program, U. S. Public Health Service, Washington, D. C. The presidential address Tuesday morning will be followed by greetings from the A. M. A., presented by Dr. Dwight Murray, Napa, Calif., President-Elect of the American Medical Association. A public meeting has been scheduled for Tuesday, 7:45 p. m., at the Bovard Auditorium, University of Southern California campus (3518 University Ave.). The guest speaker will be Goodwin J. Knight, governor of California. The general assembly will meet at the Los Angeles County General Hospital on Wednesday, where a symposium on infertility will be presented at 10 a. m. by the following panel: Dr. Lewis Michelson, San Francisco, and Dr. Sheldon A. Payne, Dr. Richard E. Ottoman, Dr. Edward T. Tyler, and James Peterson, D.D., Ph.D., Los Angeles. The golf tournament will begin Monday, 8:30 a. m., at Fox Hill Country Club golf course. The president's ball is scheduled for Thursday evening, and other social events will include a trip to Catalina, a tour of the city and Hollywood, and a barbecue Sunday at the ranch of Dr. N. Curtis King, Lake Elsinore, Calif. The woman's auxiliary will meet simultaneously.

LATIN AMERICA

ngress on Rheumatic Diseases.—The first Pan American Congress on Rheumatic Diseases will be held in Rio de Janeiro and São Paulo, Brazil, Aug. 14-20. The official subjects include: Rheumatoid Arthritis; Treatment of Rheumatoid Spondylitis; Osteoarthritis; Nonarticular Rheumatism; Rheumatic Fever; and Basic Studies of Collagen Tissue. Participants from the United States include: Dr. Robert Stecher, Cleveland, and Drs. Otto Steinbrocker, Richard H. Freyberg, and Charles Ragan, New York.

Meeting of Pacific Dermatologic Association.—The seventh annual meeting of the Pacific Dermatologic Association will convene in Mexico City Aug. 22-24 under the presidency of Dr. Maximilian E. Obermayer, Los Angeles. The session Monday morning will be held at the Institute of Cardiology, where the presidential address, "Dermatology in Mexico: A Study of Its Contributions," will be delivered at 9:45 a. m. The Monday afternoon session at the General Hospital, service of dermatology, will consist of a demonstration of leprosy by Dr. Fernando Latapí and staff, Mexico City. Tuesday morning will be devoted to a clinicopathological conference. Dr. Hamilton Montgomery, Rochester, Minn., will serve as guest moderator. A demonstration of tropical diseases other than leprosy is scheduled for Wednesday morning at the General Hospital. A joint clinical meeting will be held at the hospital in the afternoon. Patients will be presented by the Mexican Society of Dermatology. Wednesday evening there will be a banquet for members, guests, and ladies.

FOREIGN

International Medical Congress in Verona.—Under the auspices of the United Verona Hospitals, the International Medical Days will be held in Verona, Italy, Sept. 1-4, at Palazzo della Gran Guardia, Piazza Bra. The topics for discussion include: (1) the theory of stress in contemporary medicine; (2) the current problem of virus infections; and (3) cirrhosis of the liver in medicine and surgery. For information, address the International Medical Congress, % Offices of the International Verona Fair, Piazza Bra., Verona, Italy.

Australasian Medical Congress.—The ninth session of the Australasian Medical Congress (British Medical Association) will be held at Sydney, Australia, Aug. 20-27, under the presidency of Sir Archibald Collins. The New South Wales branch of the British Medical Association will act as host for the session. The subjects for the plenary sessions are Cancer; the Control of Infectious Diseases; Rehabilitation; Industrial and Occupational Hazards to Health; and Use and Abuse of Hormones in Medical Practice. Dr. Louis H. Bauer, Hempstead, N. Y., past-president of the American Medical Association, will deliver the Henry Simpson Newland Oration.

International Congress of Plastic Surgery.—Under the sponsorship of the Scandinavian Association of Plastic Surgeons, the first International Congress of Plastic Surgery will convene in Stockholm and Uppsala, Sweden, Aug. 1-5. One delegate from each country represented at the congress will meet Wednesday afternoon to discuss the formation of an International Association of Plastic Surgeons. Thursday at 8:30 a. m. there will be a bus trip to Uppsala, where scientific sessions will be followed by an exhibition of ancient medical books from the famous Waller collection at Uppsala University Library. The afternoon will be devoted to a symposium on burns, after which the group will return to Stockholm. The closing ceremony will be held at the general assembly Friday, 4-5 p. m. The social program includes a reception and cocktails in the Town Hall (Stadshuset), Stockholm, by invitation of the city council, Monday evening; a boat trip to Drottningholm Palace, royal summer residence, including a performance in its 18th century theatre, Wednesday, 5 p. m., followed by an informal congress dinner; and a banquet Friday, 7 p. m. A postcongress excursion, by boat, to the Stockholm Archipelago is projected. Among the scientific presentations will be a paper entitled "Recent Advances in Rotary Abrasive Techniques for the Correction of Acne Scars and Other Skin Defects" and a report on "Freon Mixture" by Dr. Joseph J. Eller, New York City. Dr. Morton I. Berson, New York City, will present a lecture, "Construction of Auricle," illustrated by a film showing the step-by-step construction of an auricle for complete absence, with the use of pedicle, cartilage, and split-skin grafts. Communications should be addressed to: First International Congress of Plastic Surgery, Tord Skoog, M.D., Uppsala, Sweden.

CORRECTION

Fee for Licensure.—In table 25 on page 291 of THE JOURNAL of May 28 it was indicated by a footnote that the fee for licensure on the basis of the certificate of the National Board of Medical Examiners was $25. The fee charged for license on the basis of reciprocity from another state or on the basis of credentials from the national board should have been listed as $100.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

1956 Clinical Meeting, Seattle, Nov. 27-30.

1957 Annual Meeting, New York, June 3-7.

AMERICAN MEDICAL ASSOCIATION PUBLIC RELATIONS INSTITUTE, Drake Hotel, Chicago, Aug. 31- Sept. 1. Mr. Leo E. Brown, 535 N. Dearborn St., Chicago 10, Director.

AMERICAN ASSOCIATION OF NURSING HOMES, Hotel Muehlebach, Kansas City, Mo., Sept. 19-21. Mr. Ira O. Wallace, P.O. Box 366, New Castle, Ky., Secretary.

AMERICAN ASSOCIATION OF OBSTETRICIANS, GYNECOLOGISTS AND ABDOMINAL SURGEONS, The Homestead, Hot Springs, Va., Sept. 8-10. Dr. Frank R. Lock, Bowman Gray School of Medicine, Winston-Salem, N. C., Secretary.

AMERICAN COLLEGE OF HOSPITAL ADMINISTRATORS, Convention Hall, Atlantic City, N. J., Sept. 17-19. Mr. Dean Conley, 620 North Michigan Ave., Chicago 11, Executive Director.

American Congress of Physicial Medicine and Rehabilitation, Hotel Statler, Detroit, Aug. 28-Sept. 2. Dr. Frances Baker, 30 North Michigan Ave., Chicago 2, Secretary.

American Fracture Association, Hotel Fontainebleau, Miami Beach, Fla., Sept. 19-22. Dr. Homer D. Junkin, Paris Hospital, Paris, Ill., Secretary.

American Hospital Association, Traymore Hotel, Atlantic City, N. J., Sept. 19-22. Dr. Edwin L. Crosby, 18 East Division St., Chicago 10, Director.

American Physiological Society Fall Meeting, Tufts College, Medford, Mass., Sept. 6-9. Dr. Allan C. Burton, Univ. of Western Ontario, London, Ont., Canada, Secretary.

American Roentgen Ray Society, Palmer House, Chicago, Sept. 20-23. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American Veterinary Medical Association, Radisson Hotel and Auditorium, Minneapolis, Aug. 15-18. Dr. J. G. Hardenbergh, 600 South Michigan Blvd., Chicago 5, Executive Secretary.

Biological Photographic Association, Wisconsin Hotel, Milwaukee, Aug. 30-Sept. 2. Miss Jane H. Waters, c/o Pavelle Color, Inc., 533 W. 57th St., New York 19, Executive Secretary.

Colorado State Medical Society, Shirley-Savoy Hotel, Denver, Sept. 20-23. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver 2, Executive Secretary.

Industrial Health Conference, Shamrock Hotel, Houston, Texas, Sept. 22-23. Dr. Sidney Schnur, 411 Medical Arts Bldg., Houston 2, Texas, Chairman.

Montana Medical Association, Baxter Hotel, Bozeman, Sept. 15-18. Mr. L. R. Hegland, P.O. Box 1692, Billings, Executive Secretary.

National Medical Association, Los Angeles, Aug. 8-11. Dr. John T. Givens, 1108 Church St., Norfolk 10, Va., General Secretary.

Nevada State Medical Association, Riverside Hotel, Reno, Aug. 18-20. Dr. William A. O'Brien III, 505 Chestnut St., Reno, Secretary.

New England Health Institute, Colby College, Waterville, Me., Aug. 30-Sept. 1. Dr. Edward W. Colby, City of Portland Health Dept., Portland, Me., Chairman.

Pacific Dermatologic Association, Mexico, D. F., Mexico, Aug. 22-24. Dr. Ben A. Newman, 436 N. Roxbury Drive, Beverly Hills, Calif., Secretary.

Pennsylvania, Medical Society of the State of, William Penn Hotel, Pittsburgh, Sept. 18-23. Dr. Harold B. Gardner, 230 State St., Harrisburg, Secretary.

Regional Meetings, American College of Physicians:
Jamestown, N. D., Sept. 10. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Executive Secretary.

Reno Surgical Society, Reno, Nev., Aug. 18-20. Dr. James R. Herz, 509 Humboldt St., Reno, Nev., Secretary.

Rocky Mountain Radiological Society, Shirley-Savoy Hotel, Denver, Aug. 18-20. Dr. John H. Freed, 4200 East 9th St., Denver 20, Secretary.

Society of General Physiologists, Marine Biological Laboratory, Woods Hole, Mass., Sept. 9-10. Dr. A. M. Shanes, National Institutes of Health, Bethesda 14, Md.

Southwestern Surgical Congress, Muehlebach Hotel, Kansas City, Mo., Sept. 5-7. Dr. C. M. O'Leary, 207 Plaza Court Bldg., Oklahoma City, Secretary.

U. S. Chapter, International College of Surgeons, Convention Hall, Philadelphia, Sept. 12-15. Dr. Karl Meyer, 1516 Lake Shore Drive, Chicago 10, Secretary.

Utah State Medical Association, Union Bldg., Salt Lake City, Sept. 8-10. Mr. H. Bowman, 42 S. Fifth East St., Salt Lake City 2, Executive Secretary.

Washington State Medical Association, Olympic Hotel, Seattle, Sept. 11-14. Dr. Frederick A. Tucker, 1309 Seventh Ave., Seattle 1, Secretary.

Western Association of Railway Surgeons, Las Vegas, Nev., Sept. 22-24. Dr. Leo L. Stanley, 1322 Fifth Ave., San Rafael, Calif., Secretary.

West Virginia State Medical Association, White Sulphur Springs, Aug. 18-20. Mr. Charles Lively, P. O. Box 1031, Charleston 24, Executive Secretary.

FOREIGN AND INTERNATIONAL

Australasian Medical Congress, Sydney, N.S.W., Australia, Aug. 20-27. For information write: Federal Council of the B.M.A. in Australia, 135 Macquaire St., Syndey, N.S.W., Australia.

WORLD MEDICAL ASSOCIATION, Vienna, Austria, Sept. 20-26. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

CALIFORNIA: *Written.* Los Angeles, Aug. 22-25; and Sacramento, Oct. 17-20. *Oral and Clinical Examinations for Foreign Medical School Graduates.* Los Angeles, Aug. 21; and San Francisco, Nov. 13. *Oral Examination for Reciprocity Applications.* Los Angeles, Aug. 20; and San Francisco, Nov. 12. Sec., Dr. Louis E. Jones, Room 536, 1020 N St., Sacramento.

MONTANA: *Examination and Reciprocity.* Helena, Oct. 4-5. Sec., Dr. Sidney A. Cooney, 7 West 6th Ave., Helena.

NEW HAMPSHIRE: *Examination and Reciprocity.* Concord, Sept. 14. Sec., Dr. John S. Wheeler, 107 State House, Concord.

NEW MEXICO:* *Examination and Reciprocity.* Santa Fe, Nov. 21-22. Sec., Dr. R. C. Derbyshire, 227 E. Palace Ave., Santa Fe.

[illegible]: *Endorsement.* Columbus, Aug. 29-30 and Oct. 3-4. Sec., Dr. H. M. Platter, Wyandotte Bldg., Columbus 15.

ALASKA:* On application. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

GUAM: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Sec., Dr. John E. Kennedy, Agana.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

COLORADO: *Examination.* Denver, Sept. 14-15. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

MICHIGAN: *Examination and Endorsement.* Detroit and Ann Arbor, Oct. 14-15. Sec., Mrs. Anne Baker, 410 W. Michigan Ave., Lansing 15.

OKLAHOMA: *Examination.* Oklahoma City, August 26-27. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: *Examination.* Portland, Sept. 10 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

TEXAS: *Examination.* Various cities to be determined by number of applicants from the various areas, October. Sec., Brother Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

WISCONSIN: *Examination.* Madison, Sept. 23; Milwaukee, Dec. 3. Sec., Mr. William H. Barger, 621 Ransom St., Ripon.

ALASKA: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

---

*Basic Science Certificate required.

MAGAZINE-TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of THE JOURNAL. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Monday, Aug. 1

NBC-TV, 9 p. m. EDT. "Medic" repeats "Boy in the Storm" from last season's programs.

MAGAZINES

Woman's Home Companion, August, 1955

"New Promise of Easier Childbirth," by Robert Landesman, M.D.

An assistant professor at Cornell University Medical School says "the key to medicine's new ability to make childbirth safer and easier is the recent mastering of the hormone oxytocin (Pitocin) which controls labor."

Reader's Digest, August, 1955

"This Bosom Business," by Goodrich C. Schauffler, M.D.

The author decries the "exaggerated interest in the female breast . . . stimulated by the press, the movies, TV and radio." He says "what worries most physicians is that the breasts are becoming over-emphasized symbols of sex and that their splendid biological purpose is rapidly falling into the discard." He recommends a renewed interest in breast feeding "for the health of the baby, for the health of the mother, for the pleasure of both."

"Young Man in White," by Quentin Reynolds

An ace reporter reports on a day in the life of a surgical intern. Included in the article is information on the total cost of medical education and intern and resident salaries.

"Six Ways to Beat the Heat," by Ruth and Edward Brecher

Condensed from the August issue of *Today's Health*, the article explains the workings of the body's "cooling system" and concludes with six suggestions for keeping comfortable when the mercury soars: drink liquids, increase salt intake, relax, use fans to circulate air, keep heads of small children moistened, and avoid too much exposure to sun.

Family Circle, August, 1955

"That Amazing Postnatal Recovery," by Evelyn Emig Mellon

An explanation of the puerperium period after childbirth, with a description of physical changes in the new mother's body and advice on how she should care for herself.

Redbook, August, 1955

"The Most Crucial Hour of Life," by J. D. Ratcliff

"A baby's chances of survival are greater today than ever before—and they should be even greater as we continue to unravel the mysteries of birth." According to the author, among the ways dangers are being minimized are: use of Nisentil to give the mother a high degree of pain relief with almost no unfavorable effects on the infant; availability of equipment to administer oxygen; more caution in using forceps; improved methods of handling premature babies; and "the intelligent use of Caesarean delivery." He also says childbirth should become still safer when hospitals have a device developed at Johns Hopkins Medical School that gives a continuous record of the baby's pulse during the delivery process.

Household, August, 1955

"Facial Scars—A New Cure," by Eileen Burke

"Over 500 physicians around the country—mostly dermatologists or plastic surgeons—are equipped to handle plastic planing." The process involves "freezing" the face, then planing superficial scar tissue away with a wire brush. The author quotes Dr. Abner Kurtin, who is credited with developing the process, as saying cost of the procedure would average $300.

"How It Feels to Catch Fire," by Richard Powell Carter

When the author came down with herpes zoster he started a search, first for a treatment, then for information on the condition. He reports that "there is little doubt that it is a virus" and that cortisone has been used with some success, but the medical profession has no cure.

DEATHS

Speed, Kellogg ⊕ of Highland Park, Ill., and Laguna Beach, Calif., died at the Presbyterian Hospital, Chicago, July 2, aged 76, of cardiovascular disease. Born in Cleveland Jan. 17, 1879, he graduated from the University of Chicago in 1901, B.S. cum laude, and worked from 1901 to 1902 as a graduate fellow in chemistry at the university. Before receiving his M.D. degree from Rush Medical College in 1904, he spent three months studying at the University of Leipzig and traveling in Russia, Finland, and the Scandinavian countries, then after an internship at Cook County Hospital, Chicago, he started practice in Chicago. He was associate in surgery at Rush Medical College from 1905 to 1908, when he transferred to Northwestern University Medical School, going from associate to associate professor there from 1908 to 1918. During these years he was on the staff of Mercy Hospital, Chicago. From 1912 to 1933 he was on the attending staff of Cook County Hospital. In 1919 he returned to the faculty of Rush Medical College. Starting as assistant professor, later becoming professor of surgery and at the time of his death was professor emeritus of clinical surgery (Rush) University of Illinois College of Medicine. He was attending surgeon and later consulting surgeon at the Presbyterian Hospital, Chicago, since 1919; attending surgeon, Highland Park and Lake Forest, Ill., hospitals; attending surgeon for many years at Provident Hospital, Chicago; consulting surgeon and lecturer at the U. S. Naval hospitals in San Diego, Calif., and Great Lakes, Ill., also at the Veterans Administration Hospital, Long Beach, Calif., for the past three years; honorary consulting surgeon at the Hoag Memorial (Presbyterian) Hospital, Newport Beach, Calif., also the Orange (Calif.) County General Hospital, and consulting surgeon for the Chicago, Milwaukee and St. Paul Railroad.

KELLOGG SPEED, 1879-1955

Dr. Speed was a founder-member of the American Board of Surgery and of the American Board of Orthopedic Surgery; member of the American Surgical Association since 1918, Western Surgical Association (president 1927 to 1928), Chicago Surgical Society, American Orthopedic Association, American Association for the Surgery of Trauma (first president 1938 to 1939), Societé Internationale de Chirurgie (speaker-delegate, Paris, 1920), Institute of Medicine of Chicago, and Chicago Pathological Society. He was an honorary member of the Los Angeles Surgical Society, Los Angeles Orthopedic Society, Seattle Surgical Society, Omaha Clinical Association, American Academy of Orthopaedic Surgeons, Chicago Orthopaedic Society, and the first honorary member of the Los Angeles chapter of the Western Orthopedic Association. He was a member of the board of governors, American College of Surgeons and was a trustee of Rush Medical College.

Dr. Speed was a member of the Special Committee on Fractures, Cooperative Committee, American Medical Association, from 1936 to 1951 and Chairman from 1938 to 1951. He was chairman for more than 20 years of the Chicago Regional Fracture Committee of the American College of Surgeons and was also a member of the National Committee on Trauma of the American College of Surgeons.

In 1938 he went to Australia as a guest lecturer on fractures at the University of Sydney. He was awarded a citation from the University of Chicago in 1942 and received a Certificate of Appreciation from the American Medical Association in 1951 for 25 years' service as Chairman of the Fracture Exhibit. He was given a distinguished service award from the Medical Alumni Association, University of Chicago, 1954.

The fracture service that he instituted at Cook County Hospital has been copied by many other institutions. He was instrumental in having fracture first-aid equipment installed for the first time in police cars and ambulances of Chicago. Among his original surgical methods are reduction of shoulder dislocation, fusion of the hip joint, and the anterior approach to vertebral bodies. Referring to fracture of the neck of the femur he originated the phrase "the unsolved fracture" in the oration he delivered before the Clinical Congress of the American College of Surgeons in Boston in 1934. As an operating surgeon and clinician, his methods were always conservative.

In 1916 he was sent overseas with the rank of Hon. Lieut. Col., Royal Army Medical Corps, as head of the "Murphy Unit," which was placed in command of No. 23 General Hospital, British Expeditionary Forces, at Etaples, France. From there he headed a surgical team operating behind the front lines in Belgium. There he acquired a severe Clostridium perfringens (Welch's bacillus) infection in his left hand that threatened to end his career. However, when the United States entered the war in 1917, he returned as Major, later Lieut. Col., M. C., in charge of the Surgical Division of U. S. Base Hospital 12, which took over General Hospital No. 18, British Expeditionary Force, France, in May, 1917. In 1918 he transferred to work in various mobile hospitals and evacuation centers close to the Aisne-Marne Front, Somme Offensive Lys, St. Mihiel, and Meuse-Argonne engagements. He was decorated by both the British and the United States governments.

At the close of World War I he returned for a time for further work with Sir Robert Jones of Liverpool, with whom he first studied in 1915. He was the author of the textbook, "Fractures and Dislocations," four editions (1916-1942); a monograph, "Traumatic Injuries of the Carpus," (1925); co-author of the "Primer on Fractures," American Medical Association, six editions; co-author, "Names of Surgical Operations," (1935); author of the chapter on general surgery in "History of Medical Practice in Illinois," (1850-1900) vol. 2, (1955), and some 200 articles chiefly on general surgical and orthopedic subjects.

Lowsley, Oswald Swinney ⊕ New York City; born in Santa Barbara, Calif., Sept. 4, 1884; Johns Hopkins University School of Medicine, Baltimore, 1912; specialist certified by the American Board of Urology; past-president of the American Urological Association; a fellow of the American College of Surgeons and the International College of Surgeons; member of the New York Academy of Medicine, International Society of Urology, Royal Society of Great Britain, and other scientific societies here and abroad; in 1938, president of the Society of Alumni of Bellevue; honorary professor of the University of Haiti and the University of Santo Domingo; held decorations from Brazil, Ecuador, the Dominican Republic, and the Republic of Haiti; served in the U. S. Navy during World War I; since 1942 honorary consultant to the Surgeon General of the U. S. Navy; past honorary consultant surgeon of the New York Police Department; consultant and first director of the James Buchanan Brady Foundation at New York Hospital; president and director of the Oswald Swinney Lowsley Foundation, Inc., of St. Clare's Hospital, where he was consultant in urology; consulting urologist, Hospital for Special Surgery in New York City, Peekskill (N. Y.) Hospital, Jamaica (N. Y.) Hospital, Nassau Hospital in Mineola, St. Agnes Hospital in White Plains, St. Luke's Hospital

---

⊕ Indicates Member of the American Medical Association.

in Newburgh, Monmouth Memorial Hospital in Long Branch, N. J., Fitkin Memorial Hospital in Neptune, N. J., Englewood (N. J.) Hospital, Norwalk (Conn.) Hospital, Stamford (Conn.) Hospital, Jersey City (N. J.) Medical Center, and the National Jewish Hospital in Denver; editor of "Oxford Looseleaf Urology" and "Yearbook of Urology"; joint author with Dr. T. J. Kirwin of a "Textbook of Urology," 'Urology for Nurses," and "Clinical Urology"; developed an operation for calculus in the renal pelvis, a method of repair of renal wounds, and an operation for the repair of hypospadias; died in Stamford, Conn., June 4, aged 70, of coronary thrombosis.

Poncher, Henry George ⊕ Valparaiso, Ind.; born in Odell, Ill., Feb. 14, 1902; University of Michigan Medical School, Ann Arbor, 1927; from 1924 to 1927 research assistant in the department of pediatrics at his alma mater; joined the faculty as instructor in pediatrics at the University of Illinois College of Medicine in Chicago, where he was later assistant professor, associate professor, and professor in the department of pediatrics and head of the department; was the first member of the faculty to receive in the same year two Raymond B. Allen Instructorship awards, designed to honor excellency in individual instruction rendered by faculty members to students; professor of human biology and director of student health at Valparaiso University; member of the American Pediatric Society, American Academy of Pediatrics, Central Society for Clinical Research, Chicago Pediatric Society, Society for Research in Child Development, Chicago Heart Association, American Heart Association, Institute of Medicine of Chicago, Sigma Xi, and Alpha Omega Alpha; formerly chairman of the Rheumatic Council of Chicago; on the staff of the Porter Memorial Hospital; at one time vice-chief of staff, La Rabida Jackson Park Sanitarium in Chicago; served as editor of "Yearbook of Pediatrics"; member of editorial board of *Journal of Pediatrics;* contributor of chapters on pediatrics in textbooks; died May 31, aged 3, of a heart attack.

en, Abraham Herbert ⊕ Captain, U. S. Navy, retired, Haverd, Pa.; born in Philadelphia May 21, 1881; Medico-Chirurgial College of Philadelphia, 1903; appointed a lieutenant (j. g.), Medical Corps, U. S. Navy, on May 2, 1906; advanced through the various ranks until promoted to captain July 1, 1928; placed on the retired list of officers of the Navy Jan. 1, 1943; during more than 36 years of service in the medical department of the Navy, served as district medical officer, 4th Naval District, Philadelphia; on the USS Dubuque, Washington, Connecticut, Hannibal, Texas, Maine, Olympia, and Mercy; in the Naval hospitals, Philadelphia and Las Animas, Colo.; with the 1st Provisional Regiment, U. S. Marines, in Camp Columbia, Havana, Cuba; as brigade surgeon, 1st Marine Brigade, U. S. Marine Corps, Port Au Prince, Haiti; at the Marine Barracks, Quantico, Va., and the Marine Corps Base, San Diego, Calif., at the Naval Ammunition Depot, Fort Mifflin, Pa., and at the Navy Yards, Philadelphia, and Pearl Harbor, T. H.; served at the Pharmacist's Mates' School in Portsmouth, Va.; held the Victory medal (Atlantic Fleet Clasp) and the Naval Expeditionary medal; died May 25, aged 74.

Hawk, George William ⊕ Sayre, Pa.; born in Orwin, Pa., Nov. 30, 1885; University of Pennsylvania School of Medicine, Philadelphia, 1911; member of the founders group of the American Board of Surgery; president-elect of the Medical Society of the State of Pennsylvania; helped organize the Wainwright Tumor Society, of which he was once president; past-president of the Bradford County Medical Society; member of the New York and New England Association of Railroad Surgeons and the American Association of Railway Surgeons; fellow and member of the board of governors of the American College of Surgeons; member of the osteopathic surgeons' examining board, Department of Public Instruction, State of Pennsylvania; associate in surgery, Guthrie Clinic, Robert Packer Hospital; chief surgeon for the Lehigh Valley Railroad; died June 9, aged 69, of carcinoma of the gallbladder.

Holt, William ⊕ Portland, Maine; born in Boston Jan. 9, 1888; Medical School of Maine, Portland, 1919; specialist certified by the American Board of Radiology; member of the American College of Radiology and the American Radium Society; fellow of the American College of Surgeons; a county medical examiner for many years; served as secretary-treasurer of the Cumberland County Medical Society; for one term served on the city council; past-president and vice-president of the Maine Medico-Legal Society; formerly assistant superintendent of the Charles V. Chapin Hospital and the Rhode Island General Hospital in Providence, and school physician for a year at Phillips Exeter Academy in Exeter, N. H.; radium consultant on the staff of the Maine General Hospital, where he died May 17, aged 66, of coronary thrombosis.

Dane, Walter Henry ⊕ Albuquerque, N. Mex.; born in Warsaw, Poland, May 5, 1895; Uniwersytet Jozefa Pilsaudskiego, Warszawa, Poland, 1922; specialist certified by the American Board of Otolaryngology; came to the United States in 1943 and served on the staff of several New York hospitals until 1951, at which time he moved to Albuquerque and assumed the position of chief of eye, ear, nose, and throat section of Veterans Administration Hospital; on the staffs of the Presbyterian, St. Joseph, and Bataan Memorial Methodist hospitals; died in London, England, May 18, aged 60, of coronary thrombosis, while enroute to a meeting of the International College of Surgeons in Geneva, Switzerland.

Wiltberger, Percy Barnette ⊕ Columbus, Ohio; born in Hinton, W. Va., Feb. 4, 1892; Ohio State University College of Medicine, Columbus, 1924; specialist certified by the American Board of Public Health; member of the American Academy of General Practice and the Aero Medical Association; member of the board of directors of the Ohio Academy of General Practice; past-president of the Airline Examiners Association; formerly county health commissioner; served during World Wars I and II; medical examiner for the Civil Aeronautics Administration; on the staffs of the Grant, White Cross, and St. Anthony hospitals; died May 28, aged 63, of myocardial infarction.

Weyerbacher, Arthur Ferdinand ⊕ Indianapolis; born in 1883; Indiana University School of Medicine, Indianapolis, 1909; clinical professor emeritus of general urinary surgery at his alma mater; specialist certified by the American Board of Urology; member of the American Urological Association; fellow of the American College of Surgeons; for 17 years treasurer of the Indiana State Medical Association; resigned in 1944 as a member of the city board of health; served during World War I; consultant at the St. Vincent's, Methodist, and Indianapolis General hospitals; died May 16, aged 71, of arteriosclerosis and cerebral infarction.

Van Duzen, Rex Edward ⊕ Dallas, Texas; born in Breckenridge, Mich., Nov. 15, 1893; University of Michigan Medical School, Ann Arbor, 1917; on the faculty of his alma mater, 1919-1920; in 1949 member of the House of Delegates of the American Medical Association serving as vice-chairman of its Section on Urology from 1951 to 1953, when he became chairman; member of the American Urological Association; served in France during World War I; associated with Baylor University, Parkland, Methodist, Bradford Memorial hospitals, and St. Paul's Hospital, where he died May 24, aged 61, of coronary thrombosis.

Alderman, Jerome Elliot ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, 1934; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; member of the staffs of the Syracuse Memorial, Syracuse Psychopathic, St. Joseph's, and General hospitals; consultant to the Wieting-Johnson Hospital; died in Atlantic City, N. J., May 11, aged 45, of acute coronary occlusion.

Baker, Elwood ⊕ Dermott, Ark.; Memphis (Tenn.) Hospital Medical College, 1901; served during World War II; local and dispensary surgeon for the Missouri Pacific Railway Company; died in St. Mary's Hospital May 30, aged 81, of cancer.

Bird, Benjamin W. ⊕ Princeton, W. Va.; Rush Medical College, Chicago, 1933; interned at the Illinois Central Hospital in Chicago and the Mercer Memorial Hospital in Princeton; served a residency at the Presbyterian Hospital in Chicago; president of the West Virginia Academy of Ophthalmology and Otolaryngology; died June 14, aged 48, of coronary thrombosis.

Bowman, Wilbur Morrison, Petersburg, Va.; University of Virginia Department of Medicine, Charlottesville, 1924; served during World War II; city health officer; on the staff of the Petersburg Hospital; died May 6, aged 56.

Bryant, Robert Lee ⊕ Arkadelphia, Ark.; University of Arkansas School of Medicine, Little Rock, 1932; served during World War II; member of the American Academy of General Practice; interned at St. Vincent's Infirmary in Little Rock; died May 29, aged 54.

Burleson, Joseph J. ⊕ Antoine, Ark. (licensed in Arkansas in 1903); died June 4, aged 79, of cerebral hemorrhage and chronic nephritis.

Cameron, Donald William ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1910; fellow of the American College of Surgeons; member of the Pittsburgh Academy of Medicine; served during World War I; on the staff of the Western Pennsylvania Hospital; died May 28, aged 69, of cerebral hemorrhage.

Carrier, Sydney Smith ⊕ Pittsburgh; Jefferson Medical College of Philadelphia, 1904; served during World War I; an associate member of the American Medical Association; died April 20, aged 72.

Carroll, James Vincent ⊕ North Platte, Neb.; St. Louis University School of Medicine, 1947; on the staffs of the Ogallala (Neb.) Hospital, North Platte Memorial Hospital, and St. Mary Hospital; died in Durango, Mexico, May 6, aged 34, *in an airplane accident.*

Chisholm, Roderick B., Griswold, Iowa; Trinity Medical College, Toronto, Canada, 1897; served as president of the school board; died April 5, aged 88, of pneumonia.

Cohen, Morris Aaron ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1914; served during World War I; on the staff of the Belvedere General Hospital and the Western Pennsylvania Hospital, where he died May 18, aged 63, of surgical shock, hemorrhage, and diaphragmatic hernia.

Corkill, Clifford Clayton ⊕ Douglas, Mich.; Rush Medical College, Chicago, 1925; associated with the Holland City (Mich.) Hospital and Community Hospital; formerly director of the Ontonagon-Baraga counties health unit located at Ontonagon and in charge of the Menominee County Health Department located in Menominee; died in Allegan (Mich.) Health Center May 21, aged 58, of injuries received in an automobile accident.

Fairchild, Charles Claude, Boise, Idaho; Trinity Medical College, Toronto, Canada, 1891; died May 13, aged 86, of arteriosclerotic heart disease.

Ferguson, Albert Stuart ⊕ Newburgh, N. Y.; Albany (N. Y.) Medical College, 1917; formerly health officer of Marlboro; served on the staffs of the Cornwall (N. Y.) Hospital, Highland Hospital in Beacon, Goshen (N. Y.) Hospital, and the St. Luke's Hospital; died in Marlboro May 13, aged 64, of coronary thrombosis.

Ferguson, John Robert, Providence, Ky.; Meharry Medical College, Nashville, Tenn., 1921; died April 4, aged 64, of a heart attack.

Frampton, James ⊕ Mount Pleasant, S. C.; Medical College of the State of South Carolina, Charleston, 1894; on the courtesy staff of the Roper Hospital in Charleston, where he died May 9, aged 82, of arteriosclerotic heart disease.

Friedman, Louis ⊕ New York City; New York University Medical College, New York City, 1897; an associate member of the American Medical Association; consultant surgeon at Sydenham Hospital; on the staffs of the Harlem Hospital and the New York Polyclinic Medical School and Hospital, where he died April 9, aged 79, of arteriosclerotic heart disease.

Gaston, John Campbell, Beaver Falls, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1907; member of the Medical Society of the State of Pennsylvania; on the staff of the Providence Hospital in Beaver Falls and the Beaver Valley General Hospital in New Brighton, where he died March 29, aged 74, of carcinoma of the sigmoid colon.

Gough, Lawrence Edward ⊕ Dayton, Ohio; Loyola University School of Medicine, Chicago, 1933; interned at the Good Samaritan Hospital in Cincinnati; died in the Mount Carmel Hospital, Columbus, May 26, aged 48, of myocardial infarction.

Greene, George Joseph, Cleveland; Georgetown University School of Medicine, Washington, D. C., 1930; city police surgeon; past-president of the city board of education; served during World War II; on the staff and formerly intern at St. John's Hospital; on the staff of St. Vincent's Charity Hospital, where he died June 4, aged 51, of coronary thrombosis.

Hammer, Charles Anthony, Brighton, Mich.; University of Louisville (Ky.) Medical Department, 1912; died May 11, aged 71, of coronary thrombosis.

Hangen, William Meyer, St. Louis; Barnes Medical College, St. Louis, 1908; died Feb. 3, aged 73, of carcinoma of the upper intestinal tract.

Hanson, Joel Hjalmar ⊕ San Carlos, Calif.; Jefferson Medical College of Philadelphia, 1918; died in Sequoia Hospital, Redwood City, May 30, aged 62, of rheumatic heart disease.

Hastings, James Barnard ⊕ Alton, Ill.; Washington University School of Medicine, St. Louis, 1905; in 1917 president of the Madison County Medical Society; past-president of the Alton Medical Society; plant physician for Wood River refinery of Standard Oil Company; served in France during World War I; on the staffs of the Alton Memorial Hospital and St. Joseph's Hospital, where he died May 21, aged 72, of probable cerebral vascular accident and hypertensive heart disease.

Headings, Donald Moore ⊕ Norristown, Pa.; Jefferson Medical College of Philadelphia, 1924; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; on the staffs of the Montgomery and Sacred Heart hospitals; died in Skytop, Pa., May 17, aged 55, of glioblastoma.

Henderson, Clair Abie, Savannah, Ga.; University of Georgia School of Medicine, Augusta, 1934; interned at the Greenville General Hospital; later became associated with the South Carolina State Health Department; health commissioner of Chatham County; served as commissioner of health of Terrell County with headquarters in Dawson, and of Augusta and Richmond County; killed in an automobile accident in Pensacola, Fla., May 14, aged 50.

Henry, James Clayton ⊕ East St. Louis, Ill.; Chicago College of Medicine and Surgery, 1912; veteran of the Spanish-American War; served on the staffs of St. Mary's Hospital and the Christian Welfare Hospital, where he died May 24, aged 76, of arteriosclerotic heart disease and hepatitis.

Hoag, Myrtle Anna ⊕ Buffalo; University of Buffalo School of Medicine, 1899; an associate member of the American Medical Association; died May 20, aged 87, of arteriosclerotic heart disease.

Hunt, Elbert C. ⊕ Conway, Ark. (licensed in Arkansas in 1903); died in the Conway Memorial Hospital May 1, aged 92, of uremia.

Johnson, George Monroe ⊕ Oberlin, Ohio; Rush Medical College, Chicago, 1901; veteran of the Spanish-American War and World War I; while practicing in Marshalltown, Iowa, served for nine years on the school board, of which he was president for five years; served on the staffs of St. Thomas Mercy Hospital and Evangelical Deaconess Home and Hospital, and served as president of the Y. M. C. A.; died in the Allen Memorial Hospital May 16, aged 79, of arteriosclerotic heart disease.

Kendall, Randall Palmer Jr. ⊕ Columbus, Ga.; Emory University School of Medicine, Atlanta, 1952; interned at the Columbus City Hospital; during World War II served as a pharmacist's mate in the Coast Guard; on the staffs of the Cobb Memorial Hospital and the City Hospital, where he died May 7, aged 39, of coronary thrombosis.

Kirkegaard, Smith Christian ⊕ Estherville, Iowa; University of Nebraska College of Medicine, Omaha, 1926; county coroner; on the staff of the Holy Family Hospital; died April 16, aged 65, of coronary thrombosis.

Kline, Bernard ⊕ Bridgeville, Pa.; L.R.C.P. of Edinburgh, and L.R.C.S., Edinburgh, Scotland, 1933; interned at the Passavant Hospital in Pittsburgh; specialist certified by the American Board of Psychiatry and Neurology; served during World War II; formerly on the staff of the Florida State Hospital in Chattahoochee, Fla.; member of the medical staff of Mayview (Pa.) State Hospital for six years and was assistant superintendent since last January; died in the Veterans Administration Hospital in Pittsburgh May 19, aged 46, of leukemia.

Kohlstaedt, George William ⊕ Indianapolis; Indiana University School of Medicine, Indianapolis, 1912; served during World War I; past-president of the city board of health; died in the Methodist Hospital May 17, aged 65, of pulmonary embolus and Hodgkin's disease.

Kollar, Joseph Blaine ⊕ Vero Beach, Fla.; Western Reserve University Medical Department, Cleveland, 1910; past-president and formerly a member of the state board of medical examiners; at one time practiced in Cleveland; died April 8, aged 71, of arteriosclerosis and heart disease.

Krakowski, Adam Joseph ⊕ Staten Island, N. Y.; Uniwersytet Jagielloński Wydzial Lekarski, Kracow, Poland, 1948; resident physician on the staff of the Richmond Memorial Hospital; died May 12, aged 40, of perforated duodenal ulcer.

McMahan, Alvin Mann, Duncan, Okla.; Tulane University of Louisiana School of Medicine, New Orleans, 1914; past-president of the Stephens County Medical Society; served during World War I; died in the Lindley Hospital May 30, aged 67, of cancer.

Maloney, Frank George Hiram ⊕ Madison, Wis.; University of Toronto Faculty of Medicine, Toronto, Canada, 1924; fellow of the American College of Surgeons and the International College of Surgeons; past-president of the Upper Peninsula Medical Society; on the staff of the Madison General Hospital, where he died May 15, aged 55, of myocardial infarction and coronary atherosclerosis.

Mazzoli, Albert Frederick ⊕ North Conway, N. H.; Laval University Faculty of Medicine, Quebec, Canada, 1932; local health officer; on the staff of the Memorial Hospital, where he died May 10, aged 53, of acute anterior myocardial infarction.

Miller, Edwin B. ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1897; an associate member of the American Medical Association; specialist certified by the American Board of Ophthalmology; served on the faculty of Temple University School of Medicine and the Graduate School of Medicine, University of Pennsylvania; formerly on the staffs of the Wills Eye Hospital and the Stetson Hospital, where he was chief of the eye service; died June 2, aged 83, of strangulated hernia.

Pelletier, Alfred George ⊕ Winchendon, Mass.; Laval University Faculty of Medicine, Quebec, Canada, 1898; died June 1, aged 79, of myocardial infarction.

Propst, Kenneth Edward ⊕ Green Lane, Pa.; Temple University School of Medicine, Philadelphia, 1931; president of the four Upper Perkiomen Joint School Boards; served during World War II; on the staff of the Grand View Hospital in Sellersville and the Montgomery Hospital in Norristown, where he served an internship and where he died May 4, aged 48, of coronary occlusion.

Reid, Charles Thomas ⊕ Joplin, Mo.; St. Louis University School of Medicine, 1906; veteran of the Spanish-American War; on the staffs of St. John's Hospital and the Freeman Hospital, where he died June 4, aged 80, of cerebral hemorrhage and bronchopneumonia.

Sanzone, Anthony, Brooklyn, N. Y.; Regia Università degli Studi di Roma. facoltà di Medicina e Chirurgia, Italy, 1936; member of the Medical Society of the State of New York; on the staff of St. Mary's Hospital; died June 15, aged 44, of acute myocardial infarction.

Schiffmann, Samuel, Newark, N. J.; University of Vermont College of Medicine, Burlington, 1901; member of the Medical Society of New Jersey; for many years clinic physician for the city health department; died May 30, aged 77.

Sexton, Charles Enoch ⊕ Oklahoma City; Medical College of Indiana, Indianapolis, 1898; served during World War I; died in the Veterans Administration Hospital, Wadsworth, Kan., June 4, aged 82, of coronary sclerosis.

Shambaugh, Noel Franklin ⊕ Long Beach, Calif.; University of Michigan Medical School, Ann Arbor, 1922; formerly clinical professor of medicine at University of Southern California School of Medicine in Los Angeles and on the faculty of his alma mater; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; attending physician at Los Angeles County Hospital; on the staffs of St. Mary's Long Beach Hospital and Long Beach Communit Hospital; died May 30, aged 58.

Shepard, Hiland George, Rochester, N. Y.; New York Homeopathic Medical College and Hospital, New York City, 1898; fo many years associated with the Genesee Hospital, where he wa an honorary staff member at the time of his death in the Moun Park Hospital, St. Petersburg, Fla., May 15, aged 83, of loba pneumonia.

Shouse, Edwin ⊕ Lawson, Mo.; University Medical College o Kansas City, 1899; on the staff of the Excelsior Springs (Mo Hospital and Sanitarium, where he died May 5, aged 79, o coronary occlusion.

Slavin, James Sylvester ⊕ Point Lookout, N. Y.; New Yor University Medical College, New York City, 1897; an associat member of the American Medical Association; died in Hem stead April 28, aged 83, of arteriosclerotic heart disease an diabetes mellitus.

Spira, Joseph ⊕ New York City; University and Bellevue Ho pital Medical College, New York City, 1913; died May 16, age 67, of cerebral hemorrhage.

Speegle, Andrew Arthur ⊕ Amarillo, Texas; Chicago College Medicine and Surgery, 1913; served during World War I; assoc ated with the Veterans Administration Hospital, where he di April 3, aged 65, of carcinoma of the pancreas, liver, lungs, a chest wall.

Weidlein, Ivan Ford ⊕ Cleveland; State University of Io College of Medicine, Iowa City, 1922; specialist certified by t American Board of Otolaryngology; member of the Americ Academy of Ophthalmology and Otolaryngology; on the st of the Doctors Hospital in Cleveland Heights and the Lakesi Hospital; died June 18, aged 57.

DIED WHILE IN MILITARY SERVICE

Robbin, Nathan Levy ⊕ Captain, U. S. Navy, Palo Alto, Calif.; born in Russia April 20, 1897; University of Illinois College of Medicine, Chicago, 1931; engaged in the private practice of medicine in Chicago from 1931 to 1942, when he was appointed a lieutenant commander, Medical Corps of the U. S. Naval Reserve; called to active duty April 9, 1942; promoted to captain, Medical Corps, U. S. Naval Reserve, in November, 1945; released from active duty Aug. 9, 1946; appointed a temporary captain in the Medical Corps of the U. S. Navy Oct. 11, 1946, and recalled to active duty; appointed a permanent commander in the Medical Corps of the U. S. Navy to rank from Nov. 1, 1945; promoted to permanent captain, Medical Corps, U. S. Navy, to rank from May 1, 1948; during World War I served in the Illinois National Guard; during more than 13 years' active duty in the medical department of the Navy, served in the Naval hospitals at San Diego and Shoemaker, Calif., Bainbridge, Md., Guam, Mariana Is., and Quantico, Va., with Naval Base Hospital no. 10 in Australia during World War II, and in the Naval Dispensary, San Francisco, where he was chief of the outpatient service and the eye, ear, nose, and throat department; died in the Naval Hospital, Oakland, May 24, aged 58, of acute pulmonary edema and myocardial infarction.

FOREIGN LETTERS

ARGENTINA

Census of Physicians.—The number of physicians in Argentina in December, 1954, was 22,762 for a population of 18 million, or one physician for each 800 inhabitants in the whole country and one for each 335 in the city of Buenos Aires. The present increase in the number of students is due to lack of selection, no restrictions in number, and the elimination of university fees. Medical schools are overcrowded, having inadequate space, equipment, and funds for teaching medicine according to approved modern standards. In 1953, the official number of students accepted in the first year by the six medical schools of the whole country was 7,054. In the medical school of Buenos Aires, 4,104 were accepted. It is predicted that in 1958 there will be 32,000 physicians, or about one physician for each 600 persons, according to V. E. de Pablo (*La semana médica,* May 12, 1955).

Death of Dr. Orías.—Dr. Oscar Orías, a leading physiologist, died suddenly on June 4, at the age of 49 years. He had studied with Professors B. A. Houssay of Buenos Aires, Carl J. Wiggers of Cleveland, and W. B. Cannon of Boston. On his return to Argentina, he organized a laboratory for research in cardiac physiology in the Medical School of Buenos Aires. He was named professor of physiology of the Medical School of the University of Córdoba in 1935. His published works include 'Recording and Interpretation of Cardiac Activity" (1939, in Spanish) and in collaboration with E. Braun-Menendez "Heart Sounds in Normal and Pathological Conditions" (1937, in Spanish, and 1939, in English). He also wrote the section on circulation in the textbook "Human Physiology" by Houssay, Lewis, Braun-Menendez, Hug, Foglia, and Leloir.

In 1950 he published "Cytology of Human Vagina" in collaboration with Ines L. C. de Allende. In 1943, Dr. Orías was dismissed from his chair because he signed a manifesto asking for effective democracy and American solidarity. He worked in the Instituto de Biología y Medicina Experimental during 1944 and 1945 but, when the University of Córdoba obtained its autonomy for a short time, he was called back by the Medical School only to resign in 1946. In 1947 he became the director of the Instituto de Investigación Médica-Mercedes y Martín Ferreyra in Córdoba, which was built by the Ferreyra family and was supported by private funds. Most of the equipment was given by the Rockefeller Foundation. From November, 1948, to November, 1949, he was visiting professor in the Long Island College of Medicine in Brooklyn, N. Y.

AUSTRIA

Pathology of Poliomyelitis.—At the meeting of the Society of Physicians in Vienna on April 1, Dr. Chiari reported on anatomic findings in 15 patients who died of poliomyelitis. These fatal cases included three adults, the oldest being 29 years of age. Despite a duration of the disease of only a few days, the changes observed in these fatal cases were most severe and involved not only the spinal cord and the medulla oblongata but also many portions of the brain, although the latter changes were far less severe. There were changes in the pons, thalamus, and cerebellum. In the latter organ, changes were observed not only in the area of the roof-nuclei of the vermis cerebelli but also in the molecular layer of its cortex. One is therefore justified in stressing the marked involvement of the brain as a characteristic feature in all these cases. In view of the route of infection, the changes in the follicles in the mesenteric lymph nodes were noteworthy. These consisted of karyorrhexis, proliferation of reticular cells, and deposits of acidophilic homogeneous masses in the centers of function. The microscopic aspect of the tissues was that of a severe disease of the spinal cord associated with extensive involvement of the more cephalad portions of the central nervous system.

Orthopedic Treatment of Poliomyelitis.—At the same meeting Dr. Erlacher stated that the main purpose of orthopedic treatment after the acute stage of poliomyelitis is the stabilization of the lower extremity by obtaining active cooperation as early as possible and encouraging walking with the aid of simple, lightweight splints. Contractures particularly of the knee and the hip must be prevented. With correct shifting of the axis of the knee behind and of the axis of the hip in front of the axis of gravity, an even completely paralyzed leg can be made stable again. Besides the use of mechanical devices, operation on joints and muscles may be indicated. Joints that no longer can be controlled should be put out of action by arthrodesis, but the functional deficiency is the more important the nearer the joint is located to the trunk. The speaker never performs arthrodeses of the hip, and rarely performs those of the knee, but arthrodesis of the foot is carried out frequently. Although arthrodesis destroys motion, arthrodesis of the shoulder may be associated with increased function in the presence of complete paralysis of the deltoid, because the function of the useless arm is largely restored by the muscles of the shoulder girdle. In suitable cases the movements of the joint may be stopped in only one direction by an arthroereisis. Transplantations of the tendons permit the use of active muscles for a certain function by eliminating unimportant motions. With the right indications and technique, a number of useful plastic operations on tendons, such as transplantation of the anterior tibialis muscle to the cuboid bone in patients with talipes due to paralysis, transplantation of the peroneous brevis muscle to the scaphoid bone in patients with flatfoot, and translocation of the peroneus longus muscle to the inner side of the heel in patients with talipes calcaneus are available. In a patient with a completely paralyzed foot, a division of the tendo achillis may still provide a useful stabilization of the foot.

Artificial Respiration in Acute Poliomyelitis.—At the same meeting Dr. G. Hofmann stated that problems of artificial respiration can be understood only in terms of the normal physiology of respiration and the factors responsible for circulatory shock. Early hospitalization is imperative and cooperation between various specialists, including the anesthetist, is essential. Early tracheotomy proved to be useful. High pressure respiration is necessary in patients with bulbar paralysis. The indication for treatment in the iron lung is therefore limited to patients with incomplete respiratory paralysis. Keeping the air passages free and prompt treatment of any disturbance of the respiratory mechanism are essential.

Poliomyelitis in Adults.—In the poliomyelitis epidemic of 1954 in Vienna 124 children and 61 adults were affected by the disease, a relatively high ratio of adults. The case fatality rate was higher among adults than among children. The peak point of the epidemic was in October. The peak of the epidemic usually occurs between Aug. 15 and Aug. 30. The clinical course of the disease showed a relatively high number of patients with acute ascending spinal paralysis. Encephalitic forms were observed particularly in the last phase of the epidemic. This epidemic may have been caused by various viruses.

New Group of Anticholinesterases.—At the meeting of the Society of Physicians of Vienna Feb. 25 Drs. Kraupp and Stumpf said that, as regards their chemical structures, the polymethylene-bis-carbaminoyl-trimethlammonium phenols are derived from the neostigmine molecule, in that, in the individual homologous compounds, two neostigmine molecules each are

---

[*] The items in these letters are contributed by regular correspondents in the various foreign countries.

attached to the carbamic acid nitrogen by polymethylene chains of various lengths (4 to 10 methylene groups). The pharmacological characteristics of the new class of substances are qualitatively identical with those of neostigmine, but they are much more active than neostigmine, and the duration of their action is greatly prolonged. The compounds BC 47 and BC 48, which are the most potent of this group, and in which the two neostigmine molecules are combined by 8 and 10 methylene groups, respectively, have 10 to 100 times the acetyl cholinesterase (true cholinesterase) inhibiting power of neostigmine. The stability of the enzyme inhibiting complex is also much greater, particularly in the dibasic compounds. This presumably explains the prolonged action in vivo. For instance, it could be demonstrated on rats that a single intravenous injection of 12.5 mg. of BC 48 per kilogram of body weight gave partial protection against tubocurarine chloride for a week, whereas after the same dose of neostigmine this protection lasts only two hours.

Dr. K. Pateisky gave the anticholinesterase, BC 40 (hexamethylene-bis-N-methylcarbaminoyl-m-trimethylammonium phenole), to 11 patients with myasthenia gravis and 10 normal controls. The undesirable secondary effects that result from large doses can be counteracted by atropine. The optimal intramuscular dose varies from 0.3 to 0.5 mg. in combination with 0.5 mg. of atropine. With this dosage there are no unpleasant secondary effects. The antimyasthenic effect begins 20 minutes after the injection and reaches a maximum after six hours. It retains its full effect (that is, no neostigmine is required) for 26 hours; and then a reduced dosage of neostigmine will suffice for an additional three days after the injection. When the optimal dose is administered the treatment is given at four-day intervals. With this form of treatment, the patients feel well, their appetite increases, and they gain weight. Thus BC 40 is an effective remedy for the symptomatic treatment of myasthenia gravis, and it is superior to other anticholinesterases by virtue of its potency, prolonged action, and mild side-effects.

Phlebographic Visualization of Pelvic Veins.—At the meeting of the Society of Physicians in Vienna on April 15, Dr. R. Gottlob stated that injection into the trochanter major through the spongy substance has proved to be the most effective method for the visualization of the pelvic veins. Puncture of the bone is done with an elongated needle or with a smooth, 8 cm. long bone needle. Since the time required for the passing of the contrast medium may vary with the rapidity of the blood stream, repeated use of serial exposures has been recommended for obtaining diagnostically useful pictures. Since serial angiography has various disadvantages, a small amount of ether was injected into the bone preceding the injection of the contrast medium, and the circulation time from the leg to the lung was determined. The distance that is ascertained with the aid of the circulation time is much longer than the distance that should be ascertained phlebographically. This incongruence however may be compensated for by the fact that ether is transported much faster by the blood stream than is the contrast medium. In 40 subjects it proved advantageous to wait with the exposure to light of the pelvis for as many seconds after the start of the injection of the contrast medium as the previously measured ether-time amounted to. The rapidity of the injection of the contrast medium should also be adjusted to the circulation time.

Thromboses of Pelvic Veins.—At the same meeting Dr. R. May stated that the primary indication for roentgenologic visualization of the pelvic veins is a pelvic thrombosis that has run its course. Lesions of mild degree (damage to the lateral wall and formation of collateral vessels) were treated with continued phenol blockade of the sympathetic nerve. Narrowing of the external and the common iliac veins, respectively, shown by the roentgenogram, frequently can be traced back to external compression, to a cicatricial-sclerotic transformation of the common vascular sheath. In cases of this type, hulling of the vein according to Wanke's technique is recommended. In severe cases, the main vessel has become completely obliterated and has been compensated for by anastomosis at a near point or by anastomosis with the pudendal and gluteal veins. In cases of this type some improvement still may be obtained with high sympathectomy. The most severe degree of damage is the obliteration of the distal portion of the vena cava. The severity of the clinical aspect (venous claudication and incapacity to stand erect for a long time) may be explained with the deficient compensation for the vena cava by superficial anastomosis at the abdominal wall and of the ascending lumbar veins that run along the vertebral column. The value of any operation is limited in patients of this type.

Myoglobinemia and Myoglobinuria.—At the meeting of the Society of Internal Medicine of Vienna on March 24 Kiss and Reinhart reported a study of the serum and urine of 40 patients (in whom myocardial infarction was found clinically and by electrocardiography) for myoglobin. In all but two patients, in whom the results were doubtful, the presence of myoglobin could be established in the serum as well as in the urine. The highest values were observed in the first few days after the infarction, but at the end of 14 to 16 days myoglobin was rarely found in the urine and serum. It appears that myoglobin excretion persists longest in patients in whom clinical symptoms and electrocardiographic records indicate relatively large infarcts. There is no parallelism between the excretion of myoglobin and either leukocytosis or leukopenia. The myoglobin excretion can be regarded as a direct sign of the infarction in contradistinction to the other laboratory changes after cardiac infarction, which can be regarded as nonspecific general reactions of the body indicating a general change in the sympathetic nervous system.

Acetazolamide.—Dr. F. Kaindl and his co-workers used acetazolamide for patients in the edematous stage of cardiac decompensation. Studies were made on 19 patients with regard to the diuretic effect and electrolytic changes in the urine. In about two-thirds of these patients oral administration of the drug produced a good diuretic effect, that is, the elimination of fluid was at least twice as much as in the periods preceding its administration. One tablet of acetazolamide is given on each of the firs three days, and then medication is interrupted for three days After this interval, the same dosage can be repeated. The continued administraton of the drug is ineffective, as the diuretic effect does not persist beyond the fourth day. There is also danger of acidosis with continued treatment.

Influence of Pyridoxine on Residual Nitrogen in the Blood.—At the same meeting Dr. S. Schmid reported that in a limited number of patients with renal insufficiency lowering of the level of the residual nitrogen was obtained temporarily by parenteral administration of pyridoxine. In single cases a prolonged drop in residual nitrogen was associated with simultaneous improvement of the patient's general condition. The effect of pyridoxin exhausted itself in the course of the disease. Animal experiments and reports in the literature suggest that the tubula apparatus of the kidney probably presents the point of attach by the vitamin. The mechanism of this action is unknown.

Blood Groups.—At the meeting of the Society of Physicians of Vienna on April 29 Dr. P. Speiser stated that, due to the complexity of blood groups and blood factors, a mother-child incompatibility of 87% can be expected. Although the possibility of the immunization of a mother by her fetus is great, such immunizations are nevertheless relatively rare. In law suits concerning paternity the use of hereditary factors permits the exclusion of paternity in about 63% of the cases. This percentage could be increased to 71 if such serum factors as anti-s, anti Fy^b, and anti-k (Cellano) were also considered.

Intratracheal Goiter.—At the same meeting, Dr. O. Novotny reported on a 38-year-old woman who had been subjected to tracheotomy 11 years earlier because of rapidly increasing dyspnea after thyroidectomy. She had been wearing a cannula ever since. An endotracheal goiter the size of a cherry was found, and it was removed by thermocautery. Since then the subglottic space remained free, and it was possible to remove the cannula.

Xanthomatosis of Skin.—At the meeting of the Society of Phyicians in Vienna on March 11, Dr. A. Matras reported on a woman, aged 62, who in 1949 underwent extirpation of the adnexa uteri for torsion of the pedicle of a tubo-ovarial cyst. Since 1948 she had had gallstones and a papular eruption on he lower extremities. In May, 1952, she was admitted to the hospital with generalized xanthomatosis. Since November, 1952, she had been under constant dermatological observation, because of multiple, firm, yellow, cutaneous nodules the size of a small cherry or smaller on the external surface of the arms and symmetrically on both elbows and knees. A dense crop of light yellow nodules the size of lentils was present on the buttocks and on the posterior surfaces of both thighs; there was areolar aggregation of the nodules in the gluteal region. Xanthelasma was clearly visible on the upper and lower eyelids. Examination showed elongation and diffuse dilatation of the aorta. Roentgenograms of the gallbladder revealed it to be the size of a goose egg with many niches caused by stones. Microscopic examination of the nodules revealed the typical aspect of xanthoma with many grindstone-like anisotropic crystals in the xanthomatous tissue. The serum cholesterol level, about 320 mg. per 100 cc. in 1952, showed variations up to 850 mg. per 100 cc. despite a rigid diet. Therapeutic trials with insulin and cortisone brought no improvement. In the course of treatment with heparin in 1954, constant cholesterol levels of about 450 mg. per 100 cc. were observed and the xanthomatous cutaneous manifestations receded. Intravenous infusions with 200 mg. of heparin in 500 cc. of isotonic sodium chloride solution were given for 18 days and resulted in a decrease of the cholesterol level from 750 to 423 mg. per 100 cc. and of the total lipids from 2.77 to 0.62 gm. per 100 cc.

COLOMBIA

Middle Lobe Syndrome.—Dr. C. Gómez Hurtado in *Unidia* (2:823-838 [Nov.-Dec.] 1954) reported the results of roentgenographic and bronchoscopic studies of the middle lobe syndrome, which is characterized by irreversible chronic obstructive atelectasis of the pulmonary lobar parenchyma frequently associated with a pneumonitis that may or may not be suppurative. The syndrome is caused by an early or late reaction of the bronchial lymph nodes to primary tuberculosis. Active tuberculosis and benign or malignant neoplasms have been excluded as causal factors. The authors reviewed the clinical histories of 649 patients with nontuberculous pneumonopathies. Opacities were observed in the middle lobe in 65 patients, in the lingula pulmonis in 2, and in the anterior segment of the right upper lobe in one. Thirty-nine of these 68 patients had irreversible atelectasis due to bronchostenosis, which was caused by bronchogenic carcinoma in only one. A diagnosis of middle lobe syndrome from a late reaction to primary tuberculosis with bronchial stenosis was made in the remaining 29 patients. During bronchoscopy six patients showed either anthracotic spots or rests of characteristic anthracotic fistulas suggesting the characteristic phase of anthracosis. In one of the patients the microscopic examination of the operative specimen confirmed the diagnosis.

The syndrome showed the following characteristics in the 29 patients: opacity from irreversible retraction of the middle lobe (except for one in the anterior segment of the upper lobe); frequent catarrh with cough and purulent, mucopurulent, or sanguineous expectoration; fair general health; sputum negative for tubercle bacilli, including examination of material obtained by lavage or bronchial aspiration; negative results of cytological examination for neoplastic cells; and negative results of repeated bronchoscopic examination for direct or indirect signs of bronchial neoplasms. In one patient the results of two consecutive endoscopies suggested carcinoma. The diagnosis was not confirmed at the operation or by microscopic examination of the operative specimen. The disease followed a benign course. The patients were observed for several years. The results of endoscopic examinations verified the diagnosis. The main findings were signs of peribronchial compression that may or may not be associated with chronic edema of the mucosa, total or partial obstruction due to compression, and preservation of the bronchial mobility (except in two patients who were very old). Bronchial suppuration, mucosal hypersecretion, or normal secretions were observed in the various patients. The author found a causal factor not previously reported. In six patients the disease was caused by anthracotic lymph nodes with the characteristic pigmentation of the bronchial mucosa at the point of compression or in nearby areas.

Epidemic of Equine Encephalomyelitis.—Drs. C. Sanmartin-Barberi and his co-workers in the *American Journal of Tropical Medicine and Hygiene* (3:283-294, 1954) report an investigation of an outbreak of disease in human beings characterized by a short, mild, febrile course in Espinal, Colombia. A virus, isolated from two of the patients, was identified as a strain of the virus of Venezuelan equine encephalomyelitis. Furthermore, in 10 other serums from persons bled several weeks after the clinical attack, high titers of neutralizing antibodies against these strains of the virus were demonstrated. The epizootic form of equine encephalomyelitis has been previously reported in Espinal, and the authors conclude that the equine encephalomyelitis virus is capable of causing human epidemics under natural conditions.

Rehabilitation Center.—A rehabilitation center for war veterans is proposed for the new Central Military Hospital. The board of directors of the Committee on Military Hygiene and the Central Military Hospital have invited Drs. Howard A. Rusk, Eugene J. Taylor, and Thomas Canty, all of the United States, to visit Colombia and assist in organizing the center.

New Hospital Opened.—The five-story, 650-bed Hospital Infantil of Bogotá was opened on May 13. It was built and equipped by the government with the collaboration of national philanthropists. This is the first hospital in Colombia that has been accredited by the American Hospital Association.

ENGLAND

Medical Use of Hypnosis.—A committee of the British Medical Association was appointed in November, 1953, to consider the uses of hypnosis in medical practice. After 18 months the committee reports that hypnosis is of value in the treatment of some patients and may be the treatment of choice in some who have psychosomatic disorders and psychoneurosis. It may also be of help in revealing unrecognized motives and conflicts in such conditions. As a method of treatment it has proved its ability to remove symptoms and to alter morbid habits of thought and behavior. It is therefore a proper subject for medical research. Like other remedies, hypnosis has its indications and limitations. Some enthusiastic supporters of its use fail to enumerate the contraindications and give the impression that it constitutes an approach replacing other forms of psychiatric treatment. This view is mistaken. Much knowledge and expert judgment are required to decide when hypnosis is likely to help the patient and whether it should be used alone or as a supplement to other methods of psychotherapy. For these reasons hypnosis should not be regarded as a specialty independent of psychological medicine.

In addition to the treatment of psychiatric disabilities there is a place for hypnosis in the production of anesthesia or analgesia for surgical and dental operations, and in suitable subjects it is an effective method of alleviating the pain of childbirth without interfering with the normal course of labor. It has been claimed that the shock of operative procedures can be mitigated when these are carried out under deep hypnosis, but the committee is not convinced of the validity of this claim and considers that further research on this is desirable. Hypnosis has its dangers, especially when used without proper consideration on persons predisposed, constitutionally or by the effects of disease, to severe psychoneurotic reactions or antisocial behavior. The possibility of committing crime under hypnosis cannot be ruled out. Hypnosis can result in the development of a relationship between hypnotist and subject of the same order and intensity that is often produced more slowly in the course of psychotherapy. The trained hypnotist is aware of this, but if hypnosis is applied without this knowledge and experience there is no control over the powerful emotions that may be released and much harm can be done if the technique is used by unskilled persons or in unsuitable patients. It is therefore recommended that the use of hypnosis should be confined to persons subscribing to the recognized ethical code governing the relation of physician and patient. This would not preclude its use by a suitably trained psychologist or a medical auxiliary working under the guidance of a physician. The committee recommends that medical students should be informed of the practice and therapeutic possibilities of hypnosis and that instruction in its clinical use should be given to all trainees in psychological medicine. Trainee anesthetists and obstetricians might also receive instruction. As it can achieve good results in certain patients and since its nature and mode of action are speculative, it constitutes a challenge to medical science. The main fields worthy of investigation are: (1) continuation of neurophysiological and psychological observations on hypnotism induced under controlled conditions; (2) controlled observations of its therapeutic effects in functional nervous disorders; (3) investigation of somatic disorders in the cause of which psychological factors are thought to play a major part; and (4) research into the general problem of the physician-patient relationship. Because of the relative brevity of treatment with hypnosis, such research may contribute to a solution of the problem created by the large number of people requiring psychotherapy. Since research of this kind requires the coordination of laboratory, clinical, and other studies, it might be best organized through the universities and research foundations.

Diseases from Pets.—At a meeting of the comparative medicine section of the Royal Society of Medicine in April, Professor Bedson stated that there was a group of psittacosis viruses with similar morphological and staining characteristics that both domestic and wild birds harbor. An outbreak of atypical pneumonia in the Faroe Islands was due to a psittacosis virus coming from fulmar petrels, and many human infections originating in pigeons, turkeys, ducks, chickens, pheasants, and other birds have been recorded. Cats, sheep, cattle, and laboratory mice are hosts of related viruses. There is no reliable evidence that these mammalian viruses produce infections in man, but all avian strains are capable of doing so, although psittacine birds are of more importance as carriers than nonpsittacine ones. Birds harboring the virus are usually imported ones suffering from acute disease. They excrete more virus than healthy birds. The strains of virus from psittacine birds are more virulent to man than are the ornithotic strains. Laboratory infections often occur and many patients infected in this way give no history of contact with an infected bird. The spread of infection from birds is airborne in the form of dried excreta. Attempts have been made to control the importation of parrots, but realization that nonpsittacine birds also harbor the virus has resulted in the ban being lifted in some other countries. The ban was reimposed after there was a sharp increase in the incidence of psittacosis.

Dr. A. Buxton discussed the incidence of salmonellosis among pets. Domestic dogs and cats have an infection rate of 1.5%. It may be as high as 18% in animals kept in kennels because of infected food; 26 of 98 samples of a proprietary dog food were infected with Salmonella organisms. Salmonellosis from infected pets is more readily passed on to children because they handle and fondle them more than adults do. In Britain the most prevalent type is Salmonella typhimurium. Dogs may carry several types without showing symptoms. Pigeons and even tortoises may be infected.

Mr. G. C. Brander, a veterinarian, said that insecticides and fungicides had done much to reduce parasitic and fungous infection. It is easy to treat the human being and overlook the source of infection. Immunity to parasites increases with age, but host resistance may be lowered by other infections. Parasitic infections are likely to become eczematous, and irritation might remain after the parasite has been eradicated. Lesions due to fungi in animals are often difficult to detect and tend to be deep in the hair follicle. With the exception of fungous and leptospiral infections, human infection from pets and other domestic animals is not frequent.

Resistance to Infection.—Prof. René Dubos, Rockefeller Institute, New York, guest speaker at a meeting of the Royal Society of Medicine in April, described experiments that could increase the susceptibility of mice to infection with Mycobacterium tuberculosis and Micrococcus (Staphylococcus), Salmonella, Klebsiella, and other organisms. Expectation of life is diminished when the animals are exposed to various stresses before inoculation, such as the administration of thyroxin, dinitrophenol, sodium citrate, and alpha-keto-glutarate or by deprivation of food for 36 to 48 hours. The results of starvation cannot be explained only by deprivation of calories, because low-caloric diets do not decrease the animals' resistance, nor does simple loss of weight produce the effect, for mice fed on low-protein diets are underweight but they are normally resistant to infection. The most effective way of lowering resistance is to starve the animal for 48 hours before inoculation. If mice are fed synthetic diets containing animo acids in place of protein, their susceptibility to infection is increased tenfold, but, if whole protein is added, normal resistance is restored, although not all proteins are equally effective in this respect. The results of these experiments may be explained either by increased susceptibility of the animals to the bacterial toxins or by more rapid and extensive bacterial growth. Altered tissue metabolism enhances susceptibility to infection. After fasting, mice are more sensitive to endotoxins from gram-negative organisms and to the recently isolated tuberculosis toxin.

Bacteria were injected intravenously in mice and later estimated quantitatively in various organs. One group had the standard Sherman diet, and the other was given a diet low in protein and starved for 48 hours beforehand. Ten hours later the first group had sterile blood and only a few organisms in the spleen and liver, while in the second group organisms were found in the blood and counts up to 50,000 were found in the liver and spleen. Other forms of stress, such as increased carbohydrate intake or administration of thyroxin, produced similar results. Mice are more susceptible to infection if the Krebs cycle is poisoned. Susceptibility to infection is increased by procedures resulting in at least three metabolic disorders—depletion of intracellular glycogen, reduction in the glycolytic activity of inflammatory cells, or increase in the tissue levels of certain polycarboxylic acids. These effects lead to impaired clearing power of the reticuloendothelial system, decrease in bactericidal power of the tissues, and decrease in resistance to bacterial toxins. Susceptibility to infection may change rapidly and reversibly, independent of the immunologic state, by physiological stresses. The findings in mice also suggest that the sugar-vitamin-amino acid mixtures so commonly given to patients in emergency situations may not be the best for restoring resistance.

Prof. A. Miles, director of the Lister Institute, said that the local reaction to the subcutaneous inoculation of organisms could be abolished by injecting epinephrine within four hours of bacterial inoculation. The early vascular reactions inhibited by the epinephrine are responsible for a 99% to 99.9% kill of the injected bacteria, according to the species of pathogen used. In allergic animals, though delayed allergy promotes infection with Myco. tuberculosis, the early exudation resulting from the anaphylactic element of tuberculin allergy might have survival value for the animal.

Dr. D. Long, National Institute for Medical Research, Mill Hill, said that bacterial infection was a cause of stress, which produced hormonal changes in rats and adrenocortical stimulation in man. The guinea pig responds to stress like man, can be sensitized to tuberculin, and produces antitoxin resembling that produced in man. Thyroxin-treated guinea pigs are more sensitive to intradermally injected tuberculin and produce more diphtheria antitoxin than controls. Insulin increases sensitivity to tuberculin. This may be related inversely to blood sugar levels; partial pancreatectomy prevents the increased response seen after treatment with thyroxin, which therefore acts through the islands of Langerhans. Dr. Long concluded that immunity was probably due to the balance between insulin and cortisone.

Dr. G. Meynell, Postgraduate Medical School, showed that if the gastrointestinal flora in mice was modified by the administration of streptomycin, their resistance to an oral dose of Salmonella typhimurium was decreased, and the organisms given by mouth could be recovered from the large intestine.

Physicians and Radio Performances.—Prof. L. J. Witts strongly objects to the insistence of the Central Ethical Committee of the British Medical Association on the anonymity of physicians appearing professionally in radio or television performances (*Brit. M. J.* [supp.] 1:263, 1955). He says that the committee misrepresents the conditions and purposes of radio. Scripts are carefully censored so that no self-advertisement is possible; physicians are invited to appear on the radio for education of the public and not for personal advertisement. Most physicians work within the framework of the National Health Service or other public services, and it is therefore essential that the public should be well informed about health and disease. Two important channels of education are radio and television and, if the physician appears on either of these, he must make personal contact with his audience to be a success. It is difficult to do this unless his name and status are known to the audience. Professor Witts says that the general public is entitled to know these things. Nobody wants to listen to "a physician" or "a surgeon." He thinks that the name and description of a doctor appearing should be published in the same way as it is at the head of a professional medical article. People appear on radio and television because of "the fun of doing it" and to achieve success in these mediums. They cannot be successful while remaining anonymous. To get a good audience for a radio performance one must have good material and a good reputation. One cannot have a reputation if one is not known. If physicians appearing on radio and television are to attract an audience comparable with that attained by radio personalities, they will only do so by making themselves known through a number of interesting talks or discussions under their own names. Professor Witts says that he has often broadcasted under his own name but that he has never been requested as a consequence to see a patient. The accusation of gaining patients through undue or unfair publicity does not therefore arise. The ban seems to reflect a tendency to say that what everyone cannot have no one will have. Medical radio and telecast programs are managed better in the United States, where, since there are provisions to prevent improper use of radio or television for personal advertisement, radio appearances are encouraged by the American Medical Association.

Cause of Coronary Thrombosis.—At a meeting of the Royal Society of Medicine to discuss coronary artery disease, Prof. H. W. Fullerton of Aberdeen attributed coronary thrombosis to diet. He accepted the explanation of Prof. J. B. Duguid of Durham that narrowing of the coronary arteries was due to small thrombi in the vessels becoming covered with endothelium and then organizing to form a fibrous thickening in the intima (*Lancet* 1:525, 1955). Since most mural thrombi show some fatty change they give rise to that combination of fatty change and fibrosis that is characteristic of atherosclerosis. Fullerton reviewed the evidence that atheroma is associated with a high fat intake in the diet. The growth of income is associated in Britain and the United States with an increased intake of fat in the diet and also with an increased incidence of coronary thrombosis, which is regarded as secondary to atheroma. Two other observations showed a correlation between intake of fat and the incidence of coronary thrombosis. Keys in the United States noted that the mortality from degenerative heart disease was higher in countries whose inhabitants had a high fat intake in their diet; and mortality from cardiovascular diseases decreased in Norway in World War II, when the fat ration was very low. Fullerton found experimentally that reduced clotting time was associated with the lipemia that followed a fatty meal and that this increased blood coagulability was present only when the intake of fat was high. He suggested that one factor responsible for the intermittent deposition of fibrin on the arterial intima was the ingestion of meals containing much fat. There would be much individual variation in this and also a sex difference, if this explanation were correct. The lipemia following the ingestion of fat is certainly greater in elderly subjects and in those with coronary artery disease. Fibrinolysis might also be a factor in the cause of coronary disease.

Dr. J. N. Morris, director of the Social Medical Research Unit of the Medical Research Council, considered the epidemiology of coronary atheroma. Mortality rates showed a slowing in the fall of the death rate in middle-aged men in the last 30 years; this did not apply to the death rate in women. Duodenal ulcer, ischemic heart disease, and bronchial carcinoma were mainly responsible for this. Ischemic heart disease was the largest single factor. The inhabitants of large towns and physically inactive persons were the chief sufferers; farmers and agricultural workers were particularly free of the disease. An epidemiological study of the pathology of coronary atherosclerosis was needed, and Dr. Morris had appealed to pathologists all over the country for information. Analysis of pooled hospital records showed that the proportion of men with coronary atherosclerosis increased to as high as 20 to 25% by the age of 70; the proportion with stenosis of a main coronary artery was 30 to 35%. Those dying of hypertension had more coronary atherosclerosis than others. In a fifth of the deaths from ischemic heart disease coronary atherosclerosis was not observed. The effect of lack of exercise was most marked. For example, the incidence of coronary thrombosis was much greater in omnibus drivers than in conductors, who spent much time running up and down the stairs.

Future of Medical Research.—In an address given on May 18 at the opening of the metabolic research unit set up by the Birmingham Regional Hospital Board, Prof. L. J. Witts of Oxford University deprecated the stifling effect of socialized medicine on research. "Those of us who are engaged in medical education and research fear the treason of the clerks, who wish to have everything tidy and circumscribed and who forget that the oak sheds ten thousand acorns to produce another tree and the fish spawns a million eggs to maintain the race of fishes. Research requires a spirit, not of prodigality but of magnificence. . . . We are more likely to get it from local pride than central authority." The need for local initiative is greater than ever under the National Health Service, said Professor Witts, where the risk is that enthusiasm may be stifled and everything reduced to one dead level. Referring to the important part played by the patient in medical research, he quoted from Bernard Shaw's play, "The Doctor's Dilemma." "It's always the patient who has to take the chance when an experiment is necessary, and we can find out nothing without experiment." New diseases, physical and mental, have appeared with the strain of civilized life, the change in human nutrition, the hazards of industry and transport, and the aging of the population. The need for experiment is not likely to diminish. The cooperation and the consent of the patient for this must always be obtained. If only those things are done that can be explained and agreed to by an intelligent patient, clinical research as a whole will greatly gain. Clinical research is a joint enterprise undertaken together by physician, scientist, and patient. It is no longer possible to preserve medicine as a mystery now that the state is the major supporter of medical research.

Poliomyelitis Vaccine.—The Medical Research Council has announced that a limited amount of poliomyelitis vaccine of the type used by Dr. Salk will be available in Britain this year. There will only be sufficient vaccine for the inoculation of small groups of children in a few centers where there are facilities for studying the poliomyelitis virus. The response to vaccination will be studied serologically. The council believes that this is necessary for planning the most effective use of the larger quantities of vaccine that it is hoped will become available next year. At present the use of the vaccine must be restricted to centers selected for these trials. The situation has been complicated by the refusal of the Indian government to export monkeys to Great Britain. These are used in the preparation of the vaccine. This ban was imposed four months ago after 394 monkeys were accidentally suffocated at London Airport during transit from India. Antivivisection societies are urging the Indian government to keep the ban in force. If the vaccine is to be produced in any quantity, 1,000 monkeys a month are needed from India. There are now fewer than 50 left for this purpose after producing sufficient vaccine for the trials planned by the Medical Research Council this summer. India has almost a monopoly on monkeys for medical research purposes.

John Snow Centenary.—The section of epidemiology and preventive medicine of the Royal Society of Medicine celebrated the centennial of the publication of John Snow's classic, "On the Mode of Communication of Cholera." Bradford Hill, professor of medical statistics in the University of London, effectively debunked the traditional story of Snow stopping the epidemic by removing the handle from the Broad Street pump. Snow himself never claimed that this episode halted the epidemic. The removal of the pump handle was symbolic rather than effective. Snow's fame rested securely on his theory of the mode of spread of cholera, built up by reasoning based on innumerable careful observations made personally by "shoe-leather epidemiology" in the affected area. Professor James Mackintosh, of the University of London department of public health, whose paper was read in his absence, stressed the difficulties against which Snow had to contend. Surface pumps were allowed to remain in the affected areas long after Snow's death. Snow's views were attacked in the *Times* by the Private Enterprise Association, and *Lancet* accused Snow of riding a scientific hobbyhorse by insisting on the paramount dangers of sewers.

Risks from Atom Bomb Tests.—On March 10 the Prime Minister was asked to take the initiative in proposing the establishment of a United Nations Commission to study the dangers to human beings from radiation during atom bomb tests and to seek the limitation of the number of experiments and thus prevent injury to the human race through world-wide contamination of the atmosphere. The atomic and nuclear tests carried out so far have released about the same amount of radiation in regions well away from testing ground as would be liberated during radiography of the chest. The Federation of American Scientists has proposed an immediate United Nations study of the potential genetic risks of nuclear weapon tests. The increase in radioactivity of the atmosphere from these weapons is negligible, except in the immediate vicinity of the explosion. Dr. Barnet Stross, a medical Member of Parliament, asked what research was being conducted on the problem of the increasing radioactive content of the atmosphere of London and what evidence there was of an association between this increased radioactivity and bronchial neoplasms. The Lord President replied that there is no evidence of any increased radioactivity of London air in recent years, that any radioactivity present is due to natural causes, and that there is no evidence that radioactivity is a contributory cause of bronchial carcinoma, although further investigations are being pursued on this possibility.

Dentists' Pay.—Dentists in the National Health Service had a 10% pay cut in 1950 when it was discovered by the Ministry of Health that they were earning far more than had been estimated when salary scales were drawn up. On March 17, 1955, the Minister of Health notified the British Dental Association that the salary cut of 1950 would be abolished. On March 31 the remuneration committee of the Dental Association recommended rejecting the Minister's offer because it would mean abandoning the recommendations of the Spens Committee, which had been asked to arbitrate on the matter of dentists' salaries, and the association's claim, based on them, for a scale that would produce an average net salary of $6,160 a year. After further consideration the association decided not to accept the committee's recommendations but to advise acceptance of the Minister's offer, because of the danger of refusing something palpable and embarking on an interminable series of negotiations.

Niddah and Sterility.—According to Dr. Bernard Sandler of the fertility clinic at the Manchester Victoria Memorial Jewish Hospital, *niddah* (postmenstrual abstention from coitus) is an important cause of sterility (*Brit. M. J.* **1**:1339, 1955). He quotes the example of the woman with a short menstrual cycle (e. g., 23 days), who will ovulate on about the ninth postmenstrual day. If, as often happens, she menstruates for eight days and then observes seven days' abstinence, the first coitus will not be until the 15th postmenstrual day, when the ovum is presumably dead. Every year Dr. Sandler sees a number of such patients who, wishing to become pregnant, have been subjected to much useless treatment for what is a very simple condition, once the knowledge of *niddah* is kept in mind. He recommends the administration of estrogens or, in some patients, androgens at the onset of menstruation. This postpones ovulation and allows the woman to have intercourse when the ovum is still alive.

Physician Auctions His Good Will.—When the National Health Service was introduced in 1948, all general practitioners who entered that service were promised financial compensation on retirement for loss of the good will of their practices. A physician has now auctioned his $11,450 compensation in a London auction room for $9,100. Such a thing has never been done before. The medical practice compensation is payable to a general practitioner in the National Health Service on retirement or to his dependents on his death before then. It carries with it a yearly interest of 2¾%. The physician who auctioned his compensation is the senior partner of a thriving London suburban practice. The purchaser will receive $11,450 plus the interest from the Ministry of Health when the physician dies or retires. The auctioneer stated that since the auction he has had several inquiries from other physicians interested in selling their medical practice compensation.

Abolishing the Apothecary System.—The apothecary system of measurement is to be abandoned in the British Pharmacopoeia for 1963 and subsequent editions. In 1951 the Committee on Weights and Measures Legislation, appointed by the Board of Trade, recommended that the apothecary system of measurement should be abolished after five years and that the trades and professions at present using it should replace it with the metric system. In 1953 the executive committee of the General Medical Council informed the Board of Trade that it accepted the recommendation. The compilers of the British Pharmacopoeia are agreed that the apothecary system should be eliminated from the Pharmacopoeia but believe that it would be premature to make the change as early as 1958, when the next edition is due to be published.

Slimming Reduces Gas Consumption.—An unusual angle of the present enthusiasm for slimming is the decrease in the domestic use of gas. The traditional cooked breakfast is becoming a thing of the past in many households. Many persons, especially women, now take little more than fruit juice and toast for breakfast. Another factor is the move away from home cooking as a result of factory, canteen, and school meals. Many married women are attracted into industry who previously had their midday meal at home. In addition, with both husband and wife working, ready-cooked foods simplify shopping.

Frustration in Hospital Service.—A warning of serious deterioration in the standards of hospital service was given by the president of the Association of Hospital and Welfare Administrators at the annual conference of the association. Although hospital service has improved since it became nationalized on July 5, 1948, the same feeling of frustration is found in the service that appears to be common to any service as soon as it becomes nationalized. A feeling of "couldn't care less" or "not my responsibility" appears to be creeping in.

Doctor Fined.—The Norwich Executive Council has asked the Minister of Health to withhold $588 from the remuneration of a physician under contract with the National Health Service. He was said to have given prescription forms for free drugs to private patients not in the service. He also gave another physician who was not in the service 305 prescription forms, enabling the latter's private patients to obtain free medicines. He has the right to appeal against the recommendations of the executive council.

Damages for Rheumatoid Arthritis.—A Glasgow schoolteacher, aged 28, sued the city of Glasgow for $28,000, claiming that she had contracted rheumatoid arthritis through working in a damp, badly ventilated, and poorly heated room. The case was ied before a jury, which, by a majority of seven to five, found or the plaintiff and assessed the damages at $5,600 despite the act that Dr. Dudley Hart, a rheumatologist, testified that from he point of view of causing rheumatoid arthritis, coldness and ampness had no relevance. Dr. J. P. Currie, also a rheumaologist, gave similar testimony, in support of which he pointed ut that there was no increased incidence of the disease among efrigerator workers and that fishmongers and butchers were pparently immune. Furthermore, the disease is common in pain, Switzerland, and the Arizona desert.

NDIA

Chloramphenicol in the Therapy of Venereal Diseases.—Rajam nd his co-workers (*Journal of the Indian Medical Profession,* ol. 1, no. 11, Feb., 1955) have used chloramphenicol in the reatment of syphilis, gonorrhea, chancroid, lymphogranuloma enereum, and granuloma inguinale. Chloramphenicol given ntramuscularly proved effective in the treatment of all of these diseases. Parenteral treatment gave better results than oral herapy. Treatment had to be stopped in three patients due to he development of cutaneous allergy. Routine examination of blood in all the patients treated with chloramphenicol did not eveal any harmful side-effects. The empirical dosage of chlormphenicol used for the cure of gonorrhea, chancroid, and ymphogranuloma venereum is not enough to abort a conomitant syphilitic infection during the incubation period. One atient with granuloma inguinale who was resistant to polyherapy responded to 20 grains (1.3 gm.) of chloramphenicol iven intramuscularly. The value of this drug in effecting permaent cure in early syphilis is yet to be decided. One patient came ack because of reinfection three and a half months after he was adequately treated for secondary syphilis with chlormphenicol. This may indicate that the first infection was aleady cured before he was reinfected. The high cost of the rug prevents its being used as a routine antisyphilitic measure, lthough, in penicillin-resistant patients with syphilis or gonorhea, those with granuloma inguinale who are resistant to treptomycin, and those with chancroid or lymphogranuloma enereum who have shown no improvement after sulfonamide herapy, chloramphenicol may be given intramuscularly with enefit.

Effects of Rauwolscine.—Das and his co-workers (*Indian J. M. Res.* 43:101 [Jan. 1] 1955) found Rauwolscine, an alkaloid of Rauwolfia canescens, to have a hypotensive effect. A peripheral asodilator, a sympathicolytic, a central vasotonic, and a reflexlock activity had been demonstrated earlier. The authors' reults were compared with those obtained by using alkaloids of Rauwolfia serpentina in cats and monkeys. A marked fall in peripheral resistance occurred due to vasodilation, but there was no significant alteration in the cardiac output. The effect of his alkaloid was best obtained when it was given intracisternally. ntraperitoneal injection gave an identical response when larger doses were used, but there was a long latent period when this route was used. After intravenous injection the fall in peripheral resistance was preceded by a transient period of cardiac irregularities and increased peripheral resistance. These findings hus point to a predominantly central origin of the hemodynamic response.

Median Rhomboidal Glossitis.—Dr. M. V. Sirsat has reported ix cases of median rhomboidal glossitis (*J. Indian M. A.* 124:493 April 1] 1955). This rare condition is probably congenital. It consists of a benign plaque on the tongue situated anterior to he circumvallate papillae. All six patients came to the hospital with a tentative diagnosis of carcinoma of the tongue. At the hospital the diagnosis of median rhomboidal glossitis was based on the gross features and characteristic location of the lesion. The surface of the lesion in some patients showed fissures and was smoothly glistening in others. It was painless. There was no leukoplakia in any part of the mouth. The submaxillary lymph nodes were enlarged. The characteristic site for this lesion is immune from primary carcinoma. Of 4,400 carcinomas of the tongue seen at the Tata Memorial Hospital, none arose primarily from this site. A biopsy was performed in all six instances to confirm the clinical diagnosis, and no evidence of malignancy was seen. In five instances the surface was covered with stratified epithelium. The epithelium showed acanthosis and hyperplasia with subepithelial round cell infiltration. In the sixth instance there was an exuberant growth of the epithelium, and the appearance could be mistaken for carcinoma; however, there was no evidence of anaplasia in any part of the section. No treatment is necessary, but the lesion may be excised if the patient wishes to get rid of the growth.

Melanoma of the Esophagus.—Dr. M. V. Sirsat reported that in the last 13 years only one case of malignant melanoma of the esophagus was seen at the Tata Memorial Hospital, Bombay (*Indian J. M. Sc.* 9:22 [Jan. 1] 1955). A 40-year-old man was admitted because of difficulty in swallowing solids of one year's duration. There was no pain or hematemesis. There was no evidence of a melanoma in the skin, eyes, or anal canal. A barium meal showed obstruction and presence of a tumor at the lower end of the esophagus. On esophagoscopy a cauliflower-like mass was seen on the posterior esophageal wall about 24 cm. from the incisor teeth. Biopsy showed the presence of large pleomorphic cells with an abundance of basophilic cytoplasm. The nuclei were round or ovoid with clumps of chromatin material. In the hematoxylin-eosin preparation melanin was seen as small particles in the cytoplasm, and after silver staining it was seen in large amounts intracellularly and extracellularly. The patient left the hospital against medical advice.

Antipyretic Activity of Some Indigenous Drugs.—Gujral and his co-workers (*Indian J. M. Res.* 43:89 [Jan. 1] 1955) conducted a series of animal experiments to determine the antipyretic effectiveness of 31 indigenous drugs. Aspirin was used as the standard for comparison. Fever was produced by subcutaneously injecting a 15% suspension of dried brewer's yeast and 2% acacia in isotonic sodium chloride solution. A decoction of the crude drug was introduced into the stomach. Control studies were made with a 2% solution of acacia in isotonic sodium chloride solution. The standard drug was also dissolved in a solution of 2% gum acacia in isotonic sodium chloride solution are administered orally. Only two drugs, Wrightia tinctoria (Indra Jav) and Woodfordia floribunda (Dhaya phul), appeared to be superior to aspirin in their antipyretic action. The active principles of these drugs are being studied.

Fibroma of the Frenum Linguae.—Fibroma of the frenum linguae is found exclusively in infants and disappears spontaneously after a few years. It is rare and appears at the site that is characteristic for pertussis ulcers. K. D. Shah reported a case treated successfully with chloramphenicol (*J. Indian M. A.* 24:471 [March 16] 1955). A 1-year-old boy with a pea-sized ulcer on the frenum linguae was seen. The margins of the ulcer were not raised. Although the mother's Kahn test was negative, antisyphilitic treatment was given for two months without any improvement. The lesion became nodular and developed a peduncle, and the margins became raised. It was not tender and did not bleed on touch. The child was given 50 mg. of chloramphenicol empirically three times a day. The ulcer began to diminish in size from the 4th day onward and had disappeared completely on the 10th day.

Combined Antibiotics.—Chopra and Khajuria (*Indian J. M. Res.* 43:129 [Jan. 1] 1955) have tried combinations of antibiotics with other chemotherapeutic agents with a view to broadening the antimicrobial activity of an antibiotic or reducing its toxicity. Viomycin alone is very effective against gram-negative organisms, but its toxicity is so great that it cannot be used clinically. It was found, however, that a combination of a noninhibitory concentration of viomycin with a relatively small amount of penicillin inhibited the growth of gram-negative organisms. Similarly gram-negative organisms became more susceptible to chloramphenicol when combined with noninhibitory concentrations of viomycin. The organisms tested were Salmonella typhosa, S. paratyphi, S. schottmülleri, and Escherichia coli.

ISRAEL

Myocardial Infarction.—At the 18th medical congress in Tel Aviv Dr. Z. Lewitus of the Beilinson Hospital in Petach-Tikvah reported that between June, 1946, and July, 1953, 1,828 patients with first and recurrent myocardial infarctions were diagnosed among members of the Labor Sick Fund in the coastal region; 469 of these cases (26%) were hospitalized in Beilinson Hospital. An analysis of the dates of occurrence of myocardial infarction showed that the monthly fluctuations were statistically insignificant, except for the month of October, when the decrease of the number of cases from the mean was greater than three times the standard error. These results contradicted the accepted view that the incidence of myocardial infarction is increased in the winter months. Comparing the number of cases during fall and winter with those in the hot months (spring and summer), it was found that a greater number of infarctions occurred in the hot period. In winter 207 cases occurred with 44 deaths; in summer 242 cases with 56 deaths. According to Heyer and his co-workers in Dallas, Texas, where the climate is similar to our own, a prevalence of myocardial infarctions in the hot months was noted. The *sharav* (dry, usually hot weather caused by desert winds) has been suspected of provoking myocardial infarction. Analysis of the moving average of *sharav* days in the past four or five years, compared with the moving average of the number of attacks, failed to show any significant correlation except for divergence during the months of May and October. The significant drop in the number of cases in October might be related to the prevalence of *sharav* during this month. The coefficient of correlation for those two events was 0.1, indicating a slightly diminished incidence of attacks on *sharav* days. Also the analysis of the number of attacks of the day preceding and the day following a *sharav* by the "N" method (Dull) has failed to show the supposed increase in myocardial infarctions at these times. No other correlation could be found between the occurrence of the attack and any of the known and measurable meteorologic characteristics such as temperature, relative humidity, wind strength, or amount of rain.

Public Health Progress.—Dr. H. Nelson, Chief Medical Officer of Pretoria, South Africa, praised the progress of Israel's health standards following his earlier visit in 1951 but severely criticized the neglect of preventive medicine when he reported recently to the heads of governmental and public health authorities on a month's inspection of medical services. Dr. S. Btesh, Director General of the Ministry of Health, prefaced Dr. Nelson's remarks by recalling that the visitor had presented recommendations to the government four years ago. If they had not all been implemented, it was through lack of opportunity rather than reluctance. One of Dr. Nelson's main recommendations was the concentration of all health services under the Ministry of Health. Dr. Nelson pointed out that, if government funds aided medical institutions, then the Ministry of Health should supervise their expenditure. The Labor Sick Fund is praiseworthy, but under the present division of power it exercises involuntary competition. The government allocates health budgets to local authorities without sufficient control of their activities. Some of the larger local authorities even lack qualified medical officers. Compilation of a public health act to supersede existing ordinances is advancing too slowly, due to unawareness of the need for new legislation. Such an act would define the exact responsibility of local and central governments. Local bodies now shirk their duties, vaguely outlined under the present law, and build without considering sanitary requirements. The government itself may build without the sanction of a health inspector. The act would replace the slow and involved court procedure necessary to prosecute an offender against public health. Fines heavy enough to bring home the gravity of an offense must be imposed, instead of the nominal punishment usually meted out. Dr. Nelson balanced his adverse impressions with admiration for the general rise in health. Since his earlier visit, the infant mortality rate had been lowered from 60 to 35 per 1,000. Gastroenteritis, which can be prevented by hygienic living, is still the main cause of infant deaths. Food handling has greatly improved in cleanliness, but much remains to be done.

Need for More Expansion of Medical Schools.—Fifty-three Arab and Druze students are studying at the Hebrew University this year. Thirty-five are freshmen, of whom one is the only Arab woman student at the university. Thirty-one of the 53 are in the college of humanities and social sciences (liberal arts), 4 in the college of science, 2 in the college of agriculture, 10 in the law school, and 6 in the college of medicine (one in the school of pharmacy and 2 in the school of dentistry). The demand for places in the Hebrew University-Hadassah Medical School far exceeds its capacity. There were 284 candidates for 50 places in the freshman class. The pharmacy section had 26 candidates for about 12 places, and the school of dentistry had 2 more applicants than it could accept. In the other five colleges, capacity more or less keeps pace with the pressure because lecture rooms do not limit attendance to the same extent as laboratories.

The increasing demand for medical personnel in Negeb settlements has prompted the Ministry of Health to organize thre seminars to train registered practical nurses, who will receiv 15 months tuition on condition that they afterward serve fo a year wherever the government sends them. About 35 student will attend each seminar, 7 of them being young men. At leas 50 young Arabs applied, and 18 have been accepted. The Ara graduates will staff two family health centers now being buil in the Little Triangle. A special curriculum has been devise for the course. It will qualify graduates for maternal and chil care, first aid, and dispensary work, under the guidance of fully qualified nurse or physician. The public committee for th Negeb settlement had approached the Ministry of Health wit an urgent request for nurses, but none of the 260 graduate who received their diplomas this May agreed to live in a Nege village. They all obtained posts in hospitals, institutions, urban health services. Although there are now 484 student nurse in 11 schools, this apparently large force will be depleted b young women leaving for family reasons. There was, howeve a large choice of candidates for the seminars now being arrange The Ministry of Health has also opened its first seminar fo midwives. Here, too, a year's training will be followed by year's compulsory service. A dozen practical nurses will specialize in midwifery.

ITALY

Surgery in Pulmonary Tuberculosis.—At a meeting of th Lombardy Society of Medical and Biological Sciences Professo Oselladore stated that pulmonary resection is becoming th treatment of choice for pulmonary tuberculosis, because it ca lead rapidly to the clinical healing of old and extensive lesion that did not respond to any previous treatment, even surgica Often it is less harmful to the respiratory function than collaps therapy, especially if it is performed early, and the patient ca be returned to his family and to society in a relatively sho time. This form of treatment is accepted by the patients becaus it gives quick recovery. Despite the success of this method preliminary treatment with collapse and antibiotics should b tried. The surgeon is called on to collapse the walls of the cavity Unlike simple pneumothorax, surgical collapse not only free the lung from the ribs and makes it possible for the organ t retract but also makes possible a constant pressure on the wall of the cavity after it has been collapsed. This pressure is achieved by most of the collapsing techniques. The speaker does not believe that drainage of the cavity is necessary, as is usually believed, but that it may even be dangerous. Closure of the lobar bronchus has also proved useful in favoring the recovery from cavitation. Further progress in collapse therapy can be obtained with fixation of the collapsed lung. The speaker concluded that conservative methods would prevail over the more radical methods.

orneal Alterations in Diabetic Patients.—At a meeting of the ledical Society of Parma Professor Quaranta reported that ome patients with diabetes show corneal alterations consisting f small dystrophic foci in the epithelium that stain with uorescein and that present varying morphological characteristics. Besides elements in which the predominating factor is a tate of simple epithelial impairment, there are foci in which loss of central substance surrounded by a halo of dystrophic pithelium is observed. The foci may be numerous; they do not ave a tendency to coalesce; they are situated mainly in the ower half of the cornea; and they are spread apart or assembled o form dotted areas of varying form and extent. The number f the single lesions and the area of the corneal surface involved letermine the gravity of the keratopathy. Edematous and inltrating perifocal episodes may be present, and this is the only ondition that may lead to a relative confluence of the various oci. These changes were observed in 13 of 38 diabetic patients. The condition may be unilateral or bilateral. Unilateral lesions nay disappear in the eye that was first impaired and appear later n the other eye. The fact that corneal dystrophy is often present n aged diabetic patients in poor general and ocular condition t first led to the assumption that these corneal alterations were f a general dystrophic nature rather than the expression of he diabetes. The speaker performed numerous control studies n nondiabetic persons in the same age group, but corneal esions similar to those found in the diabetic patients were not bserved in the controls.

ORWAY

ooks on Medicine for the Layman.—The educated layman in Norway has recently been cheered and at times puzzled by two ooks dealing with medical problems. Author of "Pasienten g Laegen" (The patient and the Physician) is the late Dr. Trygve raatøy, who while still quite young was put in charge of the sychiatric department of the Ullevaal Hospital. His resignaion of this appointment was tendered in protest against the tereotyped groove into which, in his opinion, hospital medical ervices had slipped. The subtitle of his book, "Fragments of a Polemic Autobiography," gives the keynote to the spirit in which e wrote. The abuses in the world of medicine at which he ilts include the fate awaiting the patient on admission to a ospital, where he has to run the gamut of many tests, unelieved by any close personal contact. From mechanized mediine, he goes on to a colorful description of the various types f physicians who have served under him, from the gifted intelectual bent on a distinguished scientific career to the obscure linician, who is more interested in his fellow beings than in medical library and who retains, until the end, the passionate ove of his patients. One of the characteristic features of this ook, raising it to the rank of a best seller, is the personal touch.

The author of the other book "Lege eller Kvaksalver?" (Phyician or Quack?) is Dr. O. J. Broch, professor of medicine at he University Hospital in Bergen. The title of this volume is nisleading, for Broch gives his readers much more than a disussion of the conflicting claims of orthodox and unorthodox medicine. Much of the book is devoted to subjects of more genral interest; to an explanation of the methods of scientific reearch, to world health problems, and to the elements of hysiology and pathology. The reader that Broch evidently had n mind is the educated layman who wants to find out the real easons for the public's love of quackery. Broch's approach is istorical, and he introduces the reader to the founders of such ogues as homeopathy, iris diagnosis, and the like. Although e defends orthodox medicine against unorthodox medicine, he dmits the mistakes of the former. He pays his readers the ompliment of not talking down to them.

nfectious Mononucleosis.—The frequency of a given disease eems to rise abruptly with our knowledge of it. In the Trondeim Central Hospital, infectious mononucleosis was represented as recently as 1948 by only 5 cases, whereas in 1952 the corresponding number was 26. In a study of 17 patients treated between 1948 and 1953, Dr. R. Savosnick points out how rare it is for this disease to be recognized before a patient is admitted to a hospital where blood cell counts are made (*Tidsskrift for den norske lægeforening,* May 1, 1955). In his series there were only eight patients in whom infectious mononucleosis was diagnosed before admission to the hospital. On the other hand, 31 were admitted with a tentative diagnosis of diphtheria and 19 with a diagnosis of angina faucium. Thirty patients were between 16 and 20 years of age; 29 were under 16, 11 of these being in the 1 to 5 year age group. Savosnick suggests that the rarity of this disease after the age of 30 may mean that most members of a given community have already suffered from it before reaching this age. He suspects that its rarity in the first half year of life may mean that the newborn infant enjoys a passive immunity transferred to it by the mother. In 40 of the author's patients, 70% of the leukocytes counted were mononuclear. Indeed, the diagnosis of infectious mononucleosis depended in all 77 patients on the demonstration of large, atypical lymphocytes. Palpable lymph nodes were also found in every patient. Two patients had visible jaundice, and it may be that the hepatic functions were more or less impaired in several others, as many other observers have found the liver involved in over 90% of their patients. The recovery of all of these patients after an average illness of 10 to 13 days did not seem to be due to modern antibiotic treatment, for the reaction was much the same whether the drug given was a sulfonamide (18 patients), penicillin (19 patients), or chlortetracycline (40 patients).

Pulmonary Embolism.—Certain textbook traditions regarding the signs of pulmonary embolism are challenged by Dr. Per Gundersen in *Nordisk medicin,* April 7. This study covers the period of Oct. 1, 1949, to Oct. 1, 1954, during which there were 119 cases of pulmonary embolism among the 10,525 admissions to the Ullevaal City Hospital in Oslo. Among the 49 patients who died of pulmonary embolism, 27 were examined post mortem. It has been taught that clinical signs of thrombophlebitis are often associated with pulmonary embolism, but this was the case with less than 10% in this series. Blood-stained expectoration has also been regarded as a common sign of pulmonary embolism, but, among the 27 patients examined post mortem, there were only 8 with such a history. On the other hand, all 27 patients were febrile, and 23 of them also suffered from dyspnea. When, therefore, an elderly patient becomes febrile and presents the findings of bronchopneumonia and when he does not respond satisfactorily to antibiotics after several days, it is well to suspect pulmonary embolism and to be prepared to give anticoagulant treatment. As was to be expected, the proportion of elderly patients in this series was high (54 of the 119 were over the age of 70), but it was more surprising that 7 of these patients had been up and about, apparently enjoying good health, when signs of pulmonary embolism set in.

Pernicious Anemia.—Norway enjoys the distinction of being the first country to include pernicious anemia among the diseases to be listed specifically as the cause of death in official returns. It has therefore been possible since 1885 to keep a check on this disease as a cause of death. That patients now die with it but not of it indicates the efficacy of modern treatment. A follow-up investigation was undertaken by Dr. P. Kolstad (*Nordisk medicin,* April 14, 1955), who traced 127 men and 170 women who were discharged from the hospital between 1935 and 1953 with a diagnosis of pernicious anemia. In this period there was a slight rise in the incidence of this disease, partly because of the upward shift of the age of the population and improved diagnostic tests. The ages of the patients ranged from 24 to 83 years when the disease was first diagnosed; 76% were between 50 and 80. At the time of the survey the duration of the disease ranged from 1 to 26 years, and 50% had been alive 7 years after the disease was diagnosed. Among the 50 patients reported as dead, the death of only 3 was attributed to pernicious anemia. Although cancer of the stomach would have killed only 13% of members of the community of the same age and sex distribution, it accounted for the death of 20 patients (40%) in this group. Apoplexy accounted for 22%, but heart disease did not figure prominently as a cause of death.

PERU

Pulmonary Resections in Tuberculosis.—Dr. Mario Molina and his co-workers reported a series of 80 patients with active pulmonary tuberculosis whose lesions varied in extent and who were unresponsive to medical therapy (*Archivos peruanos de patología y clínica*, vol. 9, no. 1, 1955). Fifty-seven patients underwent lobectomy; 12, pneumonectomy; 9, lobectomy plus segmental resection; and 2, parenchymal enucleation. The right lung was partially or totally removed in 54 patients and the left in 26. Of 24 patients who underwent either upper lobectomy or pneumonectomy without previous collapse therapy, 6 showed postoperative reactive disseminations and 2 died on the operating table. In a group of 24 patients in whom limited thoracoplasty plus apicolysis and temporary plombage, by means of Ping-Pong balls, was performed as a first stage operation, no reactive disseminations occurred, and only one patient died on the operating table. The performance of collapse procedures some time before the execution of the two types of operations mentioned diminishes the volume of the pleural cavity, thus preventing the overdistention of the unremoved part of the lung when a partial resection is made, or the harmful displacement of the mediastinum in case of total removal of the lung. On the other hand, in 48 patients in whom the Carlens double-lumen endotracheal tube was used during the operation, only one postoperative dissemination resulted, with no operative deaths; in the remaining patients in whom a simple tube was used, there were eight postoperative disseminations and three operative deaths. The authors recommended the use of the Carlens tube immediately before starting the operation, since it not only permits the complete functional independence of both lungs but also minimizes the operative hazards and the chances of postoperative tuberculous disseminations.

Of the 20 patients in whom bronchoscopy showed detectable tuberculous bronchial lesions, 11 developed fistulas as a postoperative complication (3 of these had undergone pneumonectomy and all died); lobectomy was performed on 7 and of these one died; the remaining 2 had a segmental resection and both survived. There is probably a close relationship between active bronchial tuberculosis and the development of bronchial fistulas after the surgical treatment of the disease. That this complication is one of the most dangerous for the patient who undergoes pneumonectomy must be kept in mind. Manually controlled respiration is required as it assures a quiet intrathoracic field and sharply reduces the danger of hypoxia and hypercapnia. Following exeresis, the sputum became negative in 76 of the 80 patients. The blood lost during the operation was measured so that the amount lost could be replaced as nearly as possible. The total operative mortality rate was 7.6%, but, since the introduction of collapse procedures prior to resection, the use of Carlens' tube, and controlled respiration, the mortality and morbidity rates have significantly diminished. The authors concluded that pulmonary resection is a valuable method of treatment especially when lesions not benefited by other methods have developed.

Blastomycosis.—Five cases of South American blastomycosis were reported by Morales and Romero (*Archivos peruanos de patología y clínica*, vol. 9, no. 1, 1955). This disease is uncommon in Peru as compared with other Latin American countries and is practically limited to the rural population. All of the patients were men. The diagnosis was made by finding the fungus in microscopic sections of mucocutaneous lesions or involved lymph nodes. Cultures of biopsy specimens were also positive. When bronchopulmonary involvement was suspected, sputum smears were also found to be positive. Tissue specimens were stained by Leishman's method. Some fungi presented only one bud looking like the Blastomyces dermatitidis, which causes North American blastomycosis. In all the patients positive direct and crossed skin reactions were observed. One patient who had had the disease for only a short time had disseminated mucocutaneous lesions, but he was in good general health, whereas the others had had the disease for many years and showed general lymphatic and visceral involvement and severe malnutrition. In three patients a clinical remission was obtained with sulfisoxazole (Gantrisin) and other sulfonamides, and most of the lesions healed satisfactorily. No relapses were observed. In the other two patients the subjective and clinical improvement was only fair. The authors conclude that early diagnosis and treatment markedly improve the prognosis.

Meeting of Psychiatrists.—At the first Peruvian Journeys on Psychiatry in Arequipa in April Dr. Sal y Rosas said that the number of patients with mental diseases in Peru has been steadily increasing in the last 30 years but that facilities for their care had not kept pace with this increase. The Victor Larco Herrera Hospital of Lima is the only institution in the country especially devoted to psychiatric patients. Although its original capacity of 400 beds has been increased to 1,400, the number of psychatric patients for whom adequate medical attention is lacking is still high and in many parts of the country no psychiatric services of any kind are available.

Dr. R. Jerí stated that about 50% of all the patients coming to the hospitals of Lima suffer from either primarily psychological or psychosomatic disturbances, but most of the hospitals of Lima and all of those of the other cities lack a psychiatric service. It is essential that every hospital have a well-equipped psychiatric service consisting of a psychiatrist, a clinical psychologist, a psychiatric nurse, and a psychiatric social worker. At present, since it is not possible to create such units in every hospital in the country, the general practitioner is urged to familiarize himself with the simpler psychiatric techniques so that he may better serve his patients.

Dr. Sal y Rosas, speaking on epilepsy, said that besides irritability the epileptic personality is characterized by parasociability in that there is a marked tendency to diligence, flattery, servilism, excessive courtesy, and attentiveness. The person tends to become hypersociable without realizing that he may thereby lay himself open to ridicule. This applies especially to those with idiopathic epilepsy. Electroencephalography is the most important method for diagnosing the disease, permitting in many patients with symptomatic epilepsy a localization of the irritative focus.

Medical Endowments.—Drs. Oswaldo Hercelles and Alberto Hurtado, in their visit to the United States in March, obtained valuable help from several American institutions for the better functioning of Peru's one school of medicine, San Fernando, in Lima. As a result new buildings are being erected for teaching the basic sciences, a large hall has been built at the Arzobispo Loayza Hospital for clinical teaching, and a similar hall has been built at the Santo Toribio de Mogrovejo Hospital for teaching neuropathology. The library has been entirely reorganized. Free subscriptions to several medical magazines published in the United States have been obtained and many books that the Library of Congress in Washington has declared excess are being sent to the school. The services of an expert in hospital administration have been obtained for a two-year period. The Rockefeller Foundation has made a donation of $90,000 for the department of physiopathology in charge of Dr. Hurtado. The Kellogg Foundation will continue to support the biochemistry department, whose director, Dr. Guzmán Barrón, has recently visited Harvard University. The Kellogg Foundation will also continue its aid to the Cardiology Institute of the Dos de Mayo Hospital.

Surgical Risk in the Cardiovascular Patient.—At a meeting of the Peruvian Society of Cardiology in May, Dr. Ricardo Subría reported the classification of the status of the cardiovascular system that has been developed in the cardiological departments of the Dos de Mayo Hospital and National Institute of Neoplastic Diseases in order to evaluate the surgical risk in every cardiovascular patient to be operated on. This classification, based on the clinical features, has been used in 2,684 patients in a trial to ascertain what precautions should be taken by the surgeon and the anesthesiologist before, during, and after the operation. The results so far obtained justify its use. In this classification grade 1 includes patients without cardiovascular disease; grade 2, patients with cardiac disease detectable by physical examination but without limitation of physical activity; grade 3, patients with cardiac disease resulting in slight to mild cardiac insufficiency, reflected in moderate limitation of physical activity; and grade 4, patients with cardiac disease resulting in cardiac failure, and inability to carry on any physical activity without discomfort. In 2,539 patients in grades 1 and 2, the operative mortality due to central circulatory causes was 0.1%; in 134 patients in grades 2 and 3 it was 6%; and in 11 patients in grades 3 and 4 it was 36%. Patients with severe anemia, hypertension, obesity, advanced arteriosclerosis, or chronic shock tolerated the operation and the postoperative period poorly.

Dr. Warren Honored.—Dr. Earl Warren, professor of neurosurgery of the Johns Hopkins University, Baltimore, was named honorary professor of the Universidad Nacional de San Marcos in a special session of the faculty of medicine on May 2. The nomination was made by Dr. Oscar Trelles, professor of neuropathology. Dr. Warren was also made an honorary fellow of the Peruvian Society of Neuropsychiatry and Legal Medicine.

SWITZERLAND

World Health Assembly.—The Eighth World Health Assembly held in May in Mexico City was attended by delegations from 76 member states. The purpose of this assembly was to review and examine international health work assisted by the World Health Organization on all continents and to plan future health programs. Most of the session was occupied by a study of the director-general's report of the work accomplished by the World Health Organization in 1954 and of the proposed program and budget for 1956. Dr. M. G. Candau, the director-general, explained that the two greatest challenges now facing the World Health Organization are the eradication of malaria and the use of atomic energy in medicine and public health. Ever since its inception the World Health Organization has sought to mobilize all internationally available resources to help control malaria. As a result of energetic action undertaken by national administrations, often assisted by the World Health Organization and other agencies, more than 230 million people can today be considered either freed or protected from malaria. Future efforts to bring safety to over 370 million people still exposed to malaria must consider the fact that anopheline mosquitoes, which transmit malaria, may become resistant to insecticides. For this reason, we must aim at eradication rather than control.

As the resources of the World Health Organization for the development of peaceful uses of atomic energy related to medicine and public health are limited to $42,000 in 1956, it was decided that the organization should confine its activities to international aspects that individual countries were unable to deal with. The program will therefore include the question of health protection against the effects of radiation with emphasis on protecting the community against health hazards connected with the location of atomic energy plants and the contamination of water by liquid wastes, of air by volatile materials, or of the soil and the sea by solid wastes disposed therein. This part of the program would also include the establishment of standards for radioactive material and of units of radioactivity. The World Health Organization will provide expert advice and will collect and disseminate relevant scientific information. The program will also include study of the medical use of radioisotopes in therapy, diagnosis, and research. The organization, acting as a clearing house for the exchange of information, will develop long-term help to countries in training adequate technical personnel through fellowships, consultants, study tours, and advanced training courses. The World Health Organization is also planning to convene two expert groups during 1956 in order to study various aspects of the problem.

A further decision was taken to expand the organization's antipoliomyelitis program. The existing program had included the setting up of a basic network of poliomyelitis laboratories to study the different strains of virus identified in each participating country, as well as other viruses responsible for diseases similar to poliomyelitis. These laboratories were also studying the epidemiology of poliomyelitis and were undertaking surveys of the natural immunity in different populations. The new resolution requires the preparation and distribution of standard laboratory reagents in order to facilitate the work of national poliomyelitis centers and the training of virus specialists in new tissue culture techniques.

Incompatibility of Mercaptomerin and an Anticoagulant.—A repeated check of the prothrombin time is essential for patients receiving anticoagulant therapy but in some this control does not provide a satisfactory indication of blood coagulability. Knobel and Saudan of the University of Lausanne (*Schweiz. med. Wchnschr.* 85:131, 1955) reported that the highest values were registered when the patient was given mercaptomerin combined with Marcoumar, an anticoagulant. In vitro mercury precipitates the Marcoumar. It can thus be inferred that the chemical properties of mercaptomerin and of Marcoumar might provoke in vivo, perhaps by fixation or even by precipitation, an inactivation of the Marcoumar. As soon as the mercaptomerin was replaced by a nonmercurial diuretic, the prothrombin time decreased. This incompatibility between mercaptomerin and Marcoumar should be kept in mind, because the two drugs are often given together for thromboembolic complications in patients with asystole. This incompatibility may extend to other derivatives of mercury, and even to other drugs containing heavy metals.

Cytochrome C in Inanition.—Th. Béraud and A. Vannotti of the University of Lausanne have studied the variations in cytochrome C in states of inanition of rabbits. Within the range of cellular respiratory catalyzers, this enzyme plays an important part. The question arose as to some possible alteration in the concentration of this respiratory pigment, according to the intensity of cellular combustion. A difference was noted between the concentration of cytochrome C in the livers of rabbits who had received food and those of rabbits who had eaten nothing in the previous 48 hours. The concentration of cytochromes varies with the tissues and the intensity of the respiratory metabolism. The biosynthesis of this enzyme constitutes a process that is essentially independent of the biosynthesis of hemoglobin. When combustion increases the intensity of cytochrome C synthesis parallels that of hemoglobin.

Role of Proteins in a Low-Sodium Diet.—In most studies made on salt-poor diets, the percentage of sodium is carefully established for every element of the ration, and the total caloric value of the diet is often specified, but little attention is generally given to its protein content. Dr. M. Demole, of the University of Geneva, however, calls attention to the fact that most low-sodium diets are also poor in protein. Even if the chief indications for a low-sodium diet are diseases for which the reduction of proteins is also recommended, the individual requirements of each patient must be determined to prevent nitrogen imbalance. On the other hand, in patients with hepatic cirrhosis or lipoid nephrosis a high-protein diet should be prescribed.

Vitamin B_{12} and Protein Metabolism.—By determining the concentration of amino acids in normal subjects and in those with various diseases, Wild and his co-workers (*Schweiz. med. Wchnschr.* 85:145, 1955) have demonstrated that the vitamins of the B complex stimulate the intestinal resorption and the utilization of amino acids. Alterations in the concentration of amino acids after injections of vitamin B_{12} indicate a stimulation of protein synthesis. The anabolic action of this vitamin is effective even in subjects who already have an adequate quantity of this vitamin. Vitamin B_{12} is effective in pernicious anemia only if the hepatic function is normal.

Artificial Hibernation in Pediatrics.—A. Mégevand and P. A. Messerili, who have induced artificial hibernation with chlorpromazine at the Clinic of Pediatrics of Geneva University, report remarkable results in the treatment of the neonatal accidents following disorders of oxidation and less constant results in the treatment of the infantile neurotoxic syndrome. Although chlorpromazine is practically free of any toxic effect, it should not be used on children without having established, as clearly as possible, the etiological diagnosis. Bronchopulmonary diseases and toxic comas, especially those related to barbiturates, constitute contraindications.

CORRESPONDENCE

WORLD HEALTH ORGANIZATION ASSEMBLY

To the Editor:—In view of the increasing interest shown by the medical profession in the activities of the World Health Organization, I would like to pass on my impressions of the Eighth World Health Assembly. For the first time the assembly was held in this hemisphere. Approximately 300 delegates from 75 member countries met in Mexico City, Mexico, from May 10 to May 27 to discuss problems of health throughout the world. I had the privilege to be designated by the American Medical Association to serve on the United States delegation. The most significant assembly decisions regarding program matters concerned promotion of malaria eradication on a global scale, the role of WHO in developing the peaceful uses of atomic energy, and alteration in the requirements of the international sanitary regulations. The increasing resistance to DDT shown by several of the anophelines in different parts of the world points to the need for an all-out attack on the problem of malaria before a more general resistance in the mosquito nullifies the effects of insecticide programs. The assembly decided to use $309,000 from Casual Income, in addition to the amount proposed in the director-general's budget, for the purpose of helping governments to achieve this end, primarily through consultation and the training of personnel. A fund to accept voluntary governmental and private contributions was also established to provide further help in the form of research, supplies, equipment, and services.

The assembly defined the role of the World Health Organization in the new international program to develop the peaceful uses of atomic energy. The organization will collect and disseminate scientific information on the medical and public health aspects of the program, with particular emphasis on the subjects of standards, the use of radioisotopes in therapy, diagnosis and research, and the training of personnel. The yellow fever provisions of the international sanitary regulations were discussed at length. The decision was taken, in the light of newer epidemiological knowledge, to narrow the areas against which restrictions may be placed to those areas in which yellow fever actually exists, instead of continuing to include areas in which it was once known to exist. This action will serve to expedite travel and the flow of commerce, while still providing adequate protection. The major financial issue concerned the revision of the scale of assessments. An anomalous situation has existed since the withdrawal of the "iron curtain countries" from active participation in the work of the organization. Although they have been assessed their share of the budget yearly, they have made no contribution. This year the United States delegation was instructed to press for the removal of these noncontributing countries from the 100% scale of assessments. The assembly agreed to this in principle. However, because this change, together with certain other changes also agreed to, such as bringing the WHO scale in line with the present United Nations scale would prove a financial strain to some of the poorer countries, it was decided that the change over should be a progressive one over a four year period.

I am grateful for having had the opportunity to attend this assembly. The work of the Eighth World Health Assembly once again gave positive proof of the great value of whole-hearted United States participation in the World Health Organization. Such participation helps to protect the health of Americans, at home and abroad; it furthers the progress of medicine and of the medical profession throughout the world; and possibly most important of all, it is a force in our world-wide effort to build the conditions of peace.

SENSITIVITY TO XANTHYDROL

To the Editor:—In the Feb. 26, 1955, issue of The Journal, page 719, Wendell T. Caraway, Ph.D., presented a rapi turbidimetric test for the diagnosis of uremia. In this te xanthydrol is employed to produce a suspension of the insolubl dixanthylurea. We have attempted to modify this method so a to make it applicable to the quantitative determination of bloo urea. Limited success has been attained using gum acacia as protective colloid and measuring the resultant turbidity in th electrophotometer. In the course of these experiments, both o us developed a contact dermatitis on the hands and face charac terized by marked erythema, small vesicle formation, and pruritus. This condition became apparent in both of us afte we had worked on this method for a period of three to fou weeks. To confirm our suspicion that the xanthydrol was th agent responsible for the allergic reaction, we performed a patc test on ourselves and two laboratory workers who had neve been exposed to xanthydrol. Both of us developed a positiv reaction with marked erythema at the end of 12 hours; the con trols exhibited a negative reaction. Therefore, we have conclude that there is a definite danger of skin sensitization to xanthydr after prolonged contact with this chemical. Other workers usin or planning to use xanthydrol are cautioned to avoid exposu of the skin to the reagent.

THE FAMILY PHYSICIAN

To the Editor:—In what was otherwise a scholarly and wo *man-like article in* The Journal, *page 535, June 18, 1955,* I Emil Seletz *diverges from his task of making "a plea for p vention of deaths from reversible injuries of the brain."* *chooses in one instance to describe a family doctor* who *callous enough to berate a family for summoning him* at *p. m. to attend a patient in apparent extremis. On the* very n *page he proceeds to portray what he terms* an almost everyd occurrence in *which* a *family doctor ignorantly sits* by the be side and watches his *patient* die *without lifting a finger*. T author's prose is graphically complete with *screaming* sir and newspaper headlines. On encountering these *suppose* illustrative accounts, I was constrained to glance again at magazine cover in order to be certain a copy of a popu magazine had not been picked up by mistake. It took onl moment more to find from the footnote that this paper h been read before a section of the American College of Surgeo I had hoped that this intraprofessional sniping had died a w deserved death but, alas, in the minds of some, deep conten of the general practitioner still smolders. It is regrettable t such irrelevant material should see the printed page. The effo of organizations such as the American Academy of Gene Practice (and even of the medical schools and hospitals) encourage the development of competent family doctors seriously hampered by such irresponsible remarks by an auth of a nationally distributed article. To include pointedly critic statements in a scientific paper is untrue and unfair. The auth owes an apology to all his readers.

J. L. Bordenave, M.D.
401 Campbell St.
Geneva, Ill.

To the Editor.—Dr. Emil Seletz's article in the June 18, 195 issue of The Journal, page 535, reflected, to my way of thin ing, a highly critical and caustic attitude toward the family ty of physician, and I wondered if the proofreading staff got th same impression. The first paragraph points up the derisivene nd sets the stage for two more innuendos of the same caliber. his case report he again takes a swipe at the family physician, nd finally in a most sarcastic tone he states, "A day or two ter, when the child is found unconscious, instead of consulting specialist, the family doctor rushes the child to the hospital, nd, like the traditional painting of the physician, sits by the edside and comforts the parents until the child, with the surically curable hematoma, finally dies." To be sure everybody entitled to his own opinion in regard to his fellow colleagues, ut an article in THE JOURNAL of the American Medical Association is not the place to air such views. I might suggest that the outhern California section of the American College of Sureons arrange a joint meeting with their brethren of the Amerian Academy of General Practice. Such a meeting would assure r. Seletz that the present-day family doctor is just as well ualified in his specialty as the well-trained surgeon. It would lso serve one more important purpose. It would prove to him hat the specialists and the general practitioners can and do ork harmoniously in most instances and that it is this kind f relationship that pushes medicine on to greater and greater ccomplishments.

ROBERT A. LEVENSON, M.D.
426 N. East Ave.
Vineland, N. J.

o the Editor:—After reading the article "Recent Trends in anagement of Craniocerebral Injuries" by Dr. Emil Seletz in he June 18 issue of THE JOURNAL, one wonders whether the aper was edited before it was printed. The author leaves no oubt in the mind of the reader that he holds the general practioner and the family doctor in the greatest disdain and concedes him not the slightest intelligence, either general, medical, r otherwise. Any newsman or radio commentator, glancing hrough the article, will now feel that he has an authoritative ource to condemn American medicine, since most doctors are general practice anyway. I believe Dr. Seletz's article is a lap in the face to our present system and a feather in the cap f those who are shouting for socialized medicine.

MILTON SPARK, M.D.

Waco, Texas.

NNIVERSARY OF ANTIRABIC INOCULATION

o the Editor:—On the occasion of the 70th anniversary of the rst inoculation against rabies I am submitting a translation of n excerpt from "The Life of Pasteur," by Pasteur's son-in-law, ené Vallery-Radot.

"On a Monday morning, July 6, 1885, there appeared at asteur's laboratory an Alsatian boy, nine years old, named oseph Meister, accompanied by his mother. The boy had been itten by a mad dog on the second evening preceding his visit o Pasteur. The child had been on his way to school in the own of Meissengott, near Schlestadt, when attacked by the og. He had protected his face with his hands, and hands and rms had received many bites. A passing mason drove away he dog with an iron bar and freed the child, covered with blood nd saliva. The dog ran home and bit its master, who shot it. oseph's parents were worried and consulted the local doctor, ho advised the mother to start next day for Paris, where she hould consult a man who was not a doctor, but who would e able to do whatever could be done.

"Pasteur was profoundly affected by the fourteen wounds resent on the child's limbs. Dared he risk with this child the reventive treatment which had well succeeded with dogs? The ituation was full of anguish. He helped mother and child to uitable lodgings and gave them an appointment for five o'clock hat afternoon. In the meantime he consulted the well-known hysicians Vulpian and Grancher. After their examination, they ecided that the first inoculation should be made that evening. asteur arranged for a room for child and mother in the Rollin ollege, and Joseph was soon playing with Pasteur's chickens, abbits, and guinea pigs. On July 10, Pasteur informed his son-n-law that all was well so far. However, he became anxious as the virulence of the inoculations increased. His wife wrote to her children, 'Another bad night for your father. He cannot get accustomed to the need for treating this child as a last resort, yet he knows that he cannot do otherwise.' Another letter to his son-in-law showed that Pasteur's hope was growing. 'Dear René, I think that great things are happening. Joseph Meister is going to leave the laboratory. He is very well this morning and has slept well, though not tranquilly; his appetite is good and he has no fever. One of the greatest medical feats of the century is perhaps developing, and you would greatly regret having had no share in it.'

"Pasteur was experiencing an infinite variety of emotions. Moments of hope were followed by periods of doubt and anguish, yet throughout he retained the firm desire to save this child's life. He was temporarily unable to do his regular work. Every night was uneasy and feverish. Through visions accompanying insomnia he seemed to see this child about to die, like one he had seen succumb at the Trousseau hospital. During a treatment-period of ten days, Joseph Meister received twelve inoculations. The final ones he accepted joyfully. Pasteur's nights were still cruel. Insomnia, which men of action usually escape, does not spare men of intense mental processes. Pasteur, in spite of the weight of his accumulated experience, was for the time a prey of phantoms, scarcely able to believe that his patient would not die. But the little Joseph Meister could at last return to Alsace.

"On October 26, 1885, Pasteur presented a paper to the Academy of Sciences, describing the treatment and result occurring in this case of the antirabic inoculation he had devised and thus for the first time applied to a human individual. Said the President of the Academy, 'We have the right to state that the date of the session now held here will remain forever memorable in the history of medicine and eternally glorious for French science. Onward from today, humanity is armed with the means of combating the lethality of rabies and of preventing its ravages. This we owe to Monsieur Pasteur, and we cannot have too much admiration and gratitude for efforts which have terminated in such a splendid result.'"

I knew Joseph Meister well for several years. Until his suicide in 1940, he served as warder at the Pasteur Institute and often aided me in conducting visitors to the library, crypt, and Pasteur's laboratory at the Institute. He lent me letters addressed to him by Pasteur, expressly stipulating that they should not serve for any financial return or any exploitation. Photostats were presented to the *Virginia Medical Monthly* and the John Hay Library at Brown University, Providence, R. I.

SPEED IN CARS

To the Editor:—I have read with interest the splendid editorial entitled "Wanted—Safety Devices for Automobile Passengers" (THE JOURNAL, June 11, 1955, page 482). All that was said is worthy of much consideration, but to my opinion the basic cause of many of these hazards has not been presented, namely, terrific speed. I graduated from Rush Medical College in 1894 and am still in active work in Terre Haute, Ind., at age 83. I have been in my present offices 58 years and have never been ill from the office in all these 61 years of practice. I had the first electric auto in Terre Haute and one of the first gas cars in the city. In all that time I never had one accident; I seldom exceed 55 miles per hour. I was never late for an appointment and never lost a patient from slow transportation. The point I am trying to make is that if auto manufacturers would make cars that would not travel more than 60 miles per hour we would save many, many lives and have less hysteria among our people and less work for us doctors.

FRANK E. WIEDEMANN, M.D.
Rose Dispensary Building
Terre Haute, Ind.

GOVERNMENT SERVICES

ARMY

Mass Casualties Course.—The Army Medical Service will conduct its postgraduate course on the medical care of atomic casualties at the Walter Reed Army Medical Center six times in the fiscal year beginning July 1, 1955, instead of four times a year as previously. This is being done to meet the greatly increased demand from civilian physicians throughout the country for admission to the sessions. Since a strict quota is maintained under an allotment system, applications for attendance from physicians or other qualified professional personnel must be made through their respective affiliations. In addition to the American Medical Association and the professional schools these affiliations include the U. S. Public Health Service, the Federal Civil Defense Administration, the Veterans Administration, and the armed forces medical services. Reserve medical officers may apply through the chief of their military district to the commanding general of the appropriate Army area. Enrollment for the first course has been completed, as applicants are required to file their requests four weeks in advance of the course date desired. Dates for the six courses of the year are: July 11-16; Sept. 12-21; Dec. 5-14; Jan. 30-Feb. 8; March 19-28; and June 4-13. Lodging and travel expenses for those attending the course are borne by the individual or the organization he may represent. Clearance for contact with atomic energy information is unnecessary as the course membership is entirely professional and the material used is unclassified. The course has two major assets: One is the participation method followed in the conduct of the course, and the other is the realistic approach to the situations and problems studied. A military crisis is presented after the simultaneous delivery of several bombs on military or civilian centers of population, resulting in thousands of casualties.

NAVY

Curriculum for Reserve Medical Companies.—A "package" curriculum for naval reserve medical companies has been prepared and is now being distributed to such units throughout the United States. This curriculum was developed by the Naval Medical School and the bureau of medicine and surgery. It features instruction in atomic medicine, physical standards and examinations, the U. S. reserve forces, and the Defense Department and will be a part of the training opportunities afforded the inactive medical department reservist during fiscal year 1956. The subjects for instruction are offered as a guide for 12 of the unit's 24 regularly scheduled drills. In addition to affording a detailed outline of the study subjects to be presented, the curriculum furnishes 4 textbooks; 12 lecture pamphlets; chapter 15 of the manual of the medical department; Army Regulation 40-115; a list of additional reference textbooks; a list of training films available at all district film libraries; and suggestions to instructors for an effective presentation of the subjects assigned. Considered to be the first step in prepared programs for specialized (nonpay) medical companies, plans are now under way to develop next year's curriculum featuring preventive medicine subjects.

Clinical Clerkship Training Program.—The chief of naval personnel has authorized commandants of all continental naval districts to issue orders for special active duty, with pay up to and including 60 days, to ensigns (medical), who are selected for the Naval Clinical Clerkship Training Program, beginning July 1, 1955, and continuing throughout the fiscal year of 1956. Conducted annually throughout the United States at all teaching naval hospitals, the program affords unusually interesting and informative training for the medical student and future naval reserve medical officer during his vacation from medical school.

The only student program sponsored by the Navy Departme for medical students is the Ensign 1995 (Medical) Program Eligible candidates are limited to enrolled students or to thos who have been accepted for enrollment at medical schools i the United States and Canada, accredited by the Council o Medical Education and Hospitals of the American Medical Association. All applications from civilian individuals ar processed through the U. S. Navy Offices of Naval Officer Procurement, located in various principal cities. On inquiry either in person or by mail, the officer in charge of that offi will provide information, necessary application forms, a assistance in every practicable way.

PUBLIC HEALTH SERVICE

Health Services for American Indians.—The Public Hea Service, U. S. Department of Health, Education, and Welfa announced that it is assuming responsibility for health servi for American Indians. Public Law 568 of the 83rd Congr transferred the Indian health and hospital program from Department of the Interior to the Public Health Service effect July 1. The program affects about 350,000 Indians living reservations. A division of Indian health, located in the servi bureau of medical services, has been created to administer program. Dr. James R. Shaw, a Public Health Service off who has headed the Indian health program for the past years in the Bureau of Indian Affairs, will continue in capacity as chief of the new division. Dr. Frank French Dr. Joseph Dean will continue as assistant chiefs. About 3 employees, most of whom are located in hospitals and offices in the western parts of the country, have also been tr ferred with the program.

Dr. Leonard A. Scheele, surgeon general of the Public H Service, in commenting on the transfer said: "Although municable diseases among most Americans generally yielded to modern medical treatment and public health mea preventable illnesses are accounting for half the deaths ar Indians who live on reservations. In 1950, the average a the time of death among these people was only 36. In con it was 61 among the white population. Our immediate ta to control the diseases that are taking this toll." Dr. Sc outlined plans for a twofold health program. First, the me care program will be expanded to provide clinic and ho services to as many Indians as possible who need such Fifty-six hospitals are operated by the program, and privat other nonfederal hospitals are used on a contract basis second part of the program will be to step up public healt preventive services among the Indians. This will be done th expansion of field health facilities and services, public nursing activities, maternal and child care, school health, tation, health education, and dental services. The Public Service has set up a study of the entire Indian health pr and methods for meeting it. Such a study was directed Congress, with a report of findings due in October, 1956.

Reorganization of Biologics Control Program.—A new Di of Biologics Standards will become a part of the Nation stitutes of Health. Heretofore, the biologics control progra operated as a constituent laboratory of the National biological Institute. The reorganization will result in ar mented professional staff for the new division, expansion amount of testing and plant surveillance conducted National Institutes of Health, expansion of research rela the development and control of biological products, and str ening of supporting services such as administration, management, and statistics. The creation of the new divisi become necessary in order to deal with increasingly co problems in the fields of biological products, especially vaccines. Dr. Carl L. Larson, director of the Rocky Mo Laboratory, Hamilton, Mont., has been named chief division.

COUNCIL ON MENTAL HEALTH

rom time to time the Council on Mental Health draws atten- to valuable material on psychiatry that has been developed other mental health or psychiatric agencies and has not viously been published in other journals of general circulation. he following communication, "Psychiatrically Deviated Sex enders," was formulated by the committee on forensic psy- atry of the Group for the Advancement of Psychiatry, con- ing of Drs. Philip Q. Roche, Chairman; Vernon C. Branham; lter Bromberg; Hervey Cleckley; Frank J. Curran; Manfred Guttmacher; and Leroy Maeder.

he material presented here was first published in report 9 the Group for the Advancement of Psychiatry. The com- tee also included an appendix, "Synopses of Special Sex chopath Laws, United States," which is a comparison of the te statutes dealing with sex offenders.

he purpose of the report was to bring to the attention of ponsible persons the need for new medical legislation deal- with sex offenders and to indicate that in some instances awful sex acts need to be recognized as a surface symptom a more profound psychic disturbance. The material presented e was first published in February, 1950, has been revised the committee on psychiatry and law of the Group for the vancement of Psychiatry as of November, 1954, and has n reviewed by the Council on Mental Health.

RICHARD J. PLUNKETT, M.D., *Secretary.*

YCHIATRICALLY DEVIATED SEX OFFENDERS[1]

INTRODUCTION

n recognition of the need for rational legislation dealing h sex offenders the forensic committee of the Group for the vancement of Psychiatry conducted a study from 1947 to 19.

GENERAL CONSIDERATIONS

The preponderance of persons who carry out sex offenses which they are punishable by our current laws are not in- ved in behavior fundamentally different from that common- ce in the population; such persons are not necessarily to be arded as suffering with psychiatric disorders or as socially gerous. It is said that only a small proportion of males con- ted of sex offenses have been involved in behavior that is terially different than that of most males in the population. is small group, which numbers in the neighborhood of 5 to %, is that which engages our attention as psychiatrists. nong them will be found the feeble-minded, the psychotic the so-called psychopathic individuals. They are hereinafter ignated as psychiatrically deviated sex offenders.

The first valid legislation dealing with sex offenders was passed Illinois in 1939. There are now 20 states and the District of lumbia that have statutes dealing specifically with sexual ense. Thus far, nearly all the laws adopted have defined the offender as a "psychopath," and have regarded him as men- ly ill or as mentally defective. The committee cautions against use of the appellation psychopath, in the law on several ounds. There is still little agreement on the part of psychi- ists as to the precise meaning of the term. The committee lieves that in statutes the use of technical psychiatric terms ould be avoided whenever possible. Psychiatric knowledge and minology are in a state of flux. Once having become a part public law such a term attains a fixity unresponsive to newer entific knowledge and application. Although the framers of acted legislation, aimed at the sex offender, recognize that offense may be a symptom of a kind of mental disorder, y have failed in nearly every instance to lift the recommended ocedures of trial and disposition out of the traditional crim- l process. In such procedures the psychiatrist continues to be nfined to a precarious definition (what is a psychopath), as he in most criminal procedures, and it does not seem likely at under such circumstances the psychiatrist can hope to bring fullest measure of understanding to our courts.

SEX OFFENSE AS MENTAL ILLNESS

The unlawful sexual act may be recognized as a surface symptom of a more profound psychic disturbance. In fact, the symptom may be less significant than other pathologic features of the total personality which are more often not detected without psychiatric investigation. Only the surface manifestation attracts attention because it is unlawful and punishable. If further investigation is carried out and the inner disturbance assessed, the symptom attains a new meaning and the law then may regard the act as that of an irresponsible person with a kind of mental illness. It is clear that in the legal process we should go beyond the symptomatic illegal act itself and assess the total personality to enable the courts to better achieve the aim of both community protection and individual treatment. Thus it would appear that the psychiatrically deviated sex offender should be regarded as suffering with a mental disorder and the procedure of disposition be by indeterminate commitment as provided by law for persons with mental illness. It is clear that the identification of the psychiatrically deviated sex offender and the estimate of his danger to the community are functions of which the responsibility rests largely on the psychiatric expert. They are not matters best determined singly by the judge or by the jury. The committee proposes that the disposition of the psychiatrically deviated sex offender be properly initiated by the establishment of the diagnosis of mental disorder by expert opinion. Such a diagnosis is dependent upon the following general criteria which singly or in combination should be the guide to the psychiatrist who is required to give an opinion as to the existence of mental disorder.[2]

Repetitive Compulsive Acts.—Repetitive compulsive acts having a (dynamic) pattern of similarity and carried out to the point of community intolerance. Such acts manifest heedless disregard of consequences and seek and attain ultimate expression even if momentary obstacles are encountered.

Forced Relations.—The forcing of sexual relations implies noncompliance on the part of the offended party. Forced relations may be either heterosexual or homosexual.

Age Disparity (Relations Involving One Adult).—This criterion rests upon the legal definition of minority and consent. No uniformity exists in this part of the law. The committee proposes that in remedy the legal status of persons under 21 years of age relating to sexual behavior be clarified. In general, persons under the age of 7 are legally regarded as not responsible. On the one hand this age group stands at the extreme in the scale of age disparity. On the other hand the legal definition of the minor ignores the intervening events of puberty and the large variations in physical and emotional maturity observed in many persons stamped as minors. It may be true that such persons cannot enter into contracts, but many are by endowment and training fully capable of part or exceptionally even full responsibility for sexual behavior. Thus, in the later years of childhood age disparity may diminish to a point of a day or even hours. By the same token in the later age levels the legal concepts of rape and of contributing to delinquency become increasingly untenable. The foregoing comments on the legal status of persons under 21 reflect the committee's need for further study with the help of the legal profession. At best, these are matters which call for considerable research, reinterpretation and application on the part of the legal profession. The committee recognizes that a large number of adults mutually and privately carry out illegal sexual practices with other persons of adult status. These are not to be considered as coming within the purview of the committee's legislative recommendations.

LEGISLATION

The committee is hopeful that our sex laws can be modified to correspond to modern sex knowledge with the aim that justice fit the realities of modern life in keeping with scientific psychological concepts of sexual behavior. The committee believes that there is need for a realistic assessment of the American sex laws that penalize sexual behavior; that some laws should be revised and perhaps some entirely abandoned. In operation our sex laws are harsh, too often nourish corruption and fail to protect the community from persons who are potentially dangerous. At best, they are inapplicable. Moreover, if they were strictly enforced we should be indeed witness to a colossal travesty reaching all levels of American society. Absolute law enforcement would perforce touch about 95% of the total male population. In contrast to the universality of illegal sexual behavior actually only a meager number of persons falls into the law enforcement net to suffer inordinate punishment for the conduct of the many. In one category alone recent statistical studies bring to light that 6 million homosexual acts take place each year for every 20 convictions. In the area of extramarital copulation the frequency to conviction ratio is nearly 30 to 40 million to 300.

---

[1] A poll of the GAP membership elicited a preference response almost evenly divided between the terms "disordered" and "deviated." A more definite preference was expressed favoring the term "psychiatrically" as a modifier.

[2] It is well to point out that during puberty and adolescence libidinal drives may momentarily overwhelm defenses and find outlet in an isolated act, which may be unlawful and punishable. In this age period such acts do not always portend a bad prognosis; many of these youthful offenders attain permanent mastery of their impulses toward socially and legally unacceptable forms of sexual expression.

There is great variance of the sex laws with actual human sex behavior. Such sex laws are uniform in that they permit the judge to decide the issue of delinquency on the basis of antecedents in archaic common law which are even further removed from the realities of modern life and human behavior. In some American courts the conviction of a defendant can be secured on testimony produced by an immune witness, himself tainted by participation in the illegal act.[3]

Herein is set forth a tentative proposal intended for the eventual formulation of a model for legislation applicable to sex offenders. Such legislation anticipates the participation of psychiatry in the disposition of the sex offender, having the basic aims (1) to provide realistic community security and (2) to treat and if possible restore the sex offender to social capacity.

In 1933 the Commonwealth of Pennsylvania enacted an act which permits a trial judge to require a psychiatric examination and report on any person convicted of any offense, and if such a report conveys that the defendant "though not insane is so mentally ill or mentally deficient as to make it advisable for the welfare of the defendant or the protection of the community that he or she be committed to some institution other than a county prison, workhouse, or penitentiary, the trial judge shall have the power by virtue of this act to commit such defendant to any state or county institution provided for the reception, care, treatment and maintenance of such cases or similar mental cases, in lieu of a sentence . . . and to direct the detaining of such a defendant in such institution until further order of the court." This law provides examination only for convicted individuals.

The act provides for appeals that apply in the same manner and have like effects as if the defendant were sentenced to a prison. The committee regards this law as applied to convicted offenders as commendable for both simplicity and comprehensiveness. If employed it is adequate to deal with the sex offender. It satisfies the aims of both community protection and for treatment of the sex offender under conditions favorable to restoration. If the offender is curable he can be eventually released to society; if not, he should never be released. Thus, commitment achieves what term prison sentences never achieve.[4] It should enable the psychiatrist to function more intelligently for the court, unencumbered by dubious diagnostic expedients. The law places in the hands of the trial judge the responsibility for its application. For the convicted offender this act provides for commitment in lieu of sentence, and implies that a diagnosis of mental disorder is a defense for a criminal charge. Furthermore, in effect, the act places no limitation upon the len of time for which the defendant may be held by court or in an institution for treatment of mental cases. This law h the virtue of not representing legislation aimed with bias a particular groups of offenders.[5]

The committee recommends that the examination of such defendants be made by one or more psychiatrists officially to a court clinic, or employed by a state hospital system or the absence of these by two psychiatrists appointed by the as a commission. To the basic qualifications of licensure t committee recommends that any expert meet the a minimum qualifications of no less than five years exclu practice in the diagnosis and treatment of mental disorders. T court should not be bound by the psychiatrists' findings. In ke ing with the above suggested legislative device the commit believes that selected sex offenders make satisfactory pro tioners capable of utilizing psychiatric treatment. The comm tee is unreserved in its conviction that the committed offender should be actively treated in a non-penal i The sexual offender will not loom large numerically as a h pital problem. The stigma of sex offense officially attached the sex offender committed to a penal institution creates formidable obstacle to treatment. At best consistency that if we diagnose the sex offender as mentally disordered should be treated as a mental case in a facility for that pose. The committee can visualize only one avenue of mise: commitment to a penal institution is feasible only in t event that all sentences are indeterminate and penal institutio are transformed into realistic treatment facilities.

RECOMMENDATIONS

The committee recognizes that the recommendations to f low achieve for the adult sex offender essentially the same tre ment now extended to children in juvenile court jurisdictio The committee recommends that any legislation aimed at t control and treatment of sexual behavior contain the followi elements:

Essential Element of Definition.—The essential element definition is the existence of mental illness as diagnosed by pert opinion and as satisfying the existing legal definition of same.

Basis of Jurisdiction.—The basis of jurisdiction should dep on whether there is a charge or a conviction for criminal offe

Initiation of Proceedings.—In the case of a person accu of a sex offense, upon petition and affidavit of any person upon its own initiative the court may order a psychiatric amination and report. In the case of a convicted first sex offer a psychiatric examination and report should be mandator

Tribunal and Proceedings.—The court should be one of rec and there should be no jury participation. Private hear should be discretionary with the court and hearings should held within thirty days of the petition or of the conviction.

Medical Examination and Qualification of Examiners.— psychiatrists employed by the court should be qualified by least five years of exclusive practice in the diagnosis and tr ment of mental diseases. The court should not be bound the psychiatric findings.

Effect of Commitment on Criminal Proceedings.—In the c of the convicted offender, commitment shall be in lieu of sentence to a penal institution. In the case of the accused fendant the diagnosis of mental illness shall constitute a defe to the crime.

Disposition.—The court shall have the discretionary po to commit the convicted offender as a mentally ill person t hospital facility in lieu of a sentence or to release the offe subject to special conditions of probation. In the case of accused defendant having been found mentally ill by psychi examination the commitment may be processed through the provision of the law applied to the mentally ill.

Proceedings for Release.—Proceedings for release shall initiated by the superintendent of the institution. Discharge be only by approval of the court and under conditions erally governing release of mental patients. It shall be the of the superintendent to cause to be made a psychiatric exa nation and to report the same to the court at least every months after admission of the offender to his facility.

---

3. Kinsey, A. C.: Personal communication.

4. The Criminal Law and Sexual Offenders: Report of the Joint Committee on Psychiatry and the Law, London, British Med. Assoc., 1949, pp. 24: " . . . in regard to sexual offenders, punishment without treatment is not likely to have a beneficial effect; indeed, it can make these offenders worse, and thus more likely to repeat their offences. In a high proportion of cases imprisonment without treatment may have consequences to the community even more dangerous than to the offenders themselves."

5. It should be noted that the Pennsylvania legislature has deemed this act inadequate for Pennsylvania and in 1951 adopted special legislation dealing with offenders.

6. The argument of opposition to the treatment of sex offenders in state hospitals rests on the contention that state hospitals possess inadequate facilities in both housing and personnel, that sex offenders do not mix well with others, that treatment is unsystematized and difficult, and that there are no criteria of recovery.

MISCELLANY

he following excerpts are from the June 28, 1955, issue of Congressional Record. While it is not the normal procedure THE JOURNAL *to publish material of this type, it is believed iis instance that many members of the medical profession ld like to read the statements offered by some of the ibers of the House.*—ED.

5 AMENDMENTS TO THE UNIVERSAL ITARY TRAINING AND SERVICE ACT

R. VINSON. Mr. Speaker, I call up the conference report on bill (H. R. 3005) to further amend the Universal Military ning and Service Act by extending the authority to induct ain individuals, and to extend the benefits under the Deents Assistance Act to July 1, 1959, and ask unanimous ent that the statement of the managers on the part of the se may be read in lieu of the report.

he Clerk read as follows:

STATEMENT

e managers on the part of the House at the conference on the ding votes of the two Houses on the amendments of the Senate to ill (H. R. 3005) to further amend the Universal Military Training Service Act by extending the authority to induct certain individuals, o extend the benefits under the Dependents Assistance Act to July 1, submit the following statement in explanation of the effect of the a agreed upon by the conferees and recommended in the accompanyonference report:

e Senate amendment struck out all after the enacting clause in the e bill, made several changes in the regular draft act and added separate title the extension of the Doctors Draft Act together with pecial pay for physicians and dentists.

ere were several major and some minor differences between the e version with respect to the extension of the regular draft law he amendment as passed by the Senate.

EXTENSION OF AUTHORITY TO DRAFT INDIVIDUALS UNDER THE REGULAR DRAFT

Both the House bill and the Senate amendment provided for a 4-year sion of the regular draft.

Both the House bill and the Senate amendment provided for a 4-year sion of the Dependents Assistance Act.

The House bill provided that individuals who enlist in National d units prior to attaining the age of 18½ would not be liable for tion beyond the age of 26. Under existing law such individuals are up to age 35. The Senate amendment makes such individuals for induction up to age 28. This is the first significant difference en the House bill and the Senate amendment. The House managers d to this portion of the Senate amendment.

The House bill contained an amendment which reduced the age of ity from age 35 to age 26 for an individual who was deferred for cal reasons as a result of being rejected by an Army examining n or induction station. The Senate amendment struck out this age from the House bill and thus continues in effect the present which makes these individuals liable up to age 35. The House managreed to this portion of the Senate amendment.

Both the House bill and the Senate amendment contained language e effect that the supply of an agricultural commodity may not be into consideration either in denying or granting deferments. The te amendment merely rearranged the wording of the House bill out changing the effect of the House bill in this respect. The House gers agreed to this portion of the Senate amendment.

The next difference between the House bill and the Senate amendinvolved the amount of service necessary to qualify for exemption induction on the basis of prior service. The House bill provided an individual who served honorably on active duty after September 940, for a period of 6 months or more in the Armed Forces (or 24 hs in the Public Health Service) would not be liable for induction t upon a declaration of war or national emergency by the Congress. Senate amendment provided that an individual shall be considered as fied for exemption if he served on active duty for a period of 1 year Armed Forces unless he was discharged for the convenience of the rnment after having served 6 months or more. The Senate amendalso added the Coast and Geodetic Survey to the 2-year active-duty rement to qualify for such exemption. The House managers agreed is portion of the Senate amendment.

The Senate amendment provided for the exemption from registration induction of members of the Reserve components of the Armed s while employed as veterinarians of the United States Department griculture. This same provision was also applied to prior-service ptions by another subsection of the Senate amendment which prothat no member of a Reserve component "who has been employed as a veterinarian by the United States Department of Agriculture for a period of 24 months from and after the date of enactment of this paragraph shall be liable for induction except in time of war or national emergency declared by the Congress."

The House managers objected to this portion of the Senate amendment on the grounds that these civilian employees of the Department of Agriculture are not serving in such employment as members of the uniformed services. The Senate managers receded from their insistence on this portion of the Senate amendment.

8. The Senate amendment also added a new exemption from induction of any person who, subsequent to June 24, 1948, served on active duty for a period of not less than 18 months in the armed forces of a nation with which the United States is associated in mutual defense activities if the country of which such person is a citizen grants the same privilege to citizens of the United States. A similar proposal was contained in H. R. 9007 which passed the House in the last Congress, but did not pass the Senate. The House managers agreed to this portion of the Senate amendment.

EXTENSION OF THE DOCTORS DRAFT ACT

The Senate amendment added a separate title to the bill as it passed the House under which the Doctors Draft Act would be extended for 2 years, and entitlement to the additional extra pay for doctors would be continued for doctors entering on active duty prior to July 1, 1959. In addition, the Senate amendment contained an amendment to the Doctors Draft Act which provided that an individual after July 1, 1955, who had attained the 35th anniversary of the date of his birth and applied for a commission in one of the Armed Forces as a physician or dentist, and who was thereafter rejected for such commission on the grounds of physical disqualification, would no longer be liable for service under the doctors draft law.

In extending the Doctors Draft Act the Senate amendment made no change in the maximum age of liability of induction for physicians and dentists which, under existing law, is 51 years of age.

The House managers insisted that the age of liability for doctors under the Doctors Draft Act be substantially reduced from the present age of 51. The House managers attempted to reduce the age of liability to 41 on the grounds that this would provide physicians to take care of the medical needs of the Armed Forces for the next 2 years so long as no medical-school graduates are deferred during the next 2 years for purposes of residency training. Failing in this effort, the House managers attempted to reduce the age to 42, 43, 44, and 45, but in each instance the Senate managers insisted that the age of liability remain at 51. The Senate managers insisted that the availability of physicians numberswise was not the sole criterion with regard to the procurement of physicians. The Senate managers likewise insisted that any age below 50 with regard to the Doctors Draft Act would fail to take into consideration any upward revision in the strength of the Armed Forces during the next 2 years. The Senate managers were of the opinion that members of the uniformed services are entitled to the best possible medical care and that such medical care would not be available unless more experienced physicians and specialists served side by side with young men who have recently completed their internships. The House managers fully concur in the absolute need for experienced physicians for our Armed Forces. The Senate managers insisted that specialists, in particular, would not be available in adequate numbers if the draft age were reduced below 46. In view of the urgency of the situation and the insistence of the Senate managers, the House managers agreed to a maximum draft age under the Doctors Draft Act of 46. In other words, no doctor will be liable for service under the doctors draft law after attaining his 46th birthday.

The House managers, however, after agreeing to a draft age of 46 for doctors, insisted that any doctor over the age of 35 who had applied for a commission as a physician or dentist in one of the Armed Forces and had been rejected at any time, or is hereafter rejected, on the sole basis of a physical disqualification should no longer be liable for service under the doctors draft law. The Senate managers agreed to this amendment to the Senate amendment.

The managers of the House and Senate likewise discussed the situation with regard to optometrists. Both the House and Senate managers are conscious of the fact that the Department of the Army are using optometrists in their professional capacity as enlisted men. It is the opinion of both the House and Senate managers that the armed services should, if they utilize optometrists in their professional capacities, offer such individuals commissions. In other words, if an optometrist who is inducted under the regular draft act is utilized as an optometrist he should be offered a commission commensurate with his professional attainment.

There was no disagreement between the House and Senate managers with regard to the continuation of existing law, which authorizes additional pay for doctors serving on active duty.

CARL VINSON,
OVERTON BROOKS,
PAUL J. KILDAY,
DEWEY SHORT,
L. C. ARENDS,
Managers on the Part of the House.

MR. VINSON (interrupting the reading). Mr. Speaker, in view of the fact that the report and the statement of the conferees have been printed in the *Record* for the last 2 days, I ask unanimous consent that further reading of the statement may be dispensed with and that it be printed in the *Record* at this point.

The Speaker pro tempore. The gentleman from Georgia is recognized for 1 hour.

MR. VINSON. Mr. Speaker, the conference report before the House deals with four very essential laws affecting our national security. These laws are the basic props of our national defense and must be passed before July 1—2 days hence.

What are these laws?

First. It extends the authority to induct men into the Armed Forces as regular registrants under the regular draft law.

Second. It extends the Dependents Assistance Act—the act under which enlisted personnel receive additional allowances from the Government for their dependents.

Now both the Dependents Assistance Act and the Draft Act are to be extended for 4 years.

Third. The conference report provides for the extension of the Doctors Draft Act for 2 years, and

Fourth. It provides for the continuation of special pay for doctors who enter on active duty prior to July 1, 1959.

Now, Mr. Speaker, last February 8, this House passed, by a vote of 394 to 4, the regular draft law.

In this same bill we passed the extension of the Dependents Assistance Act.

The House Committee on Armed Services did not attach the extension of the Doctors Draft Act to the regular draft, but instead reported a separate bill, H. R. 6057 to the House.

This report was filed on May 10, and on that same day I requested the Rules Committee to hold a hearing on the bill H. R. 6057 in order that we might debate this matter before the House in the Committee of the Whole.

We appeared before the Committee on Rules on May 17.

On June 17, 4 months and 9 days after the House passed the draft extension bill, the Senate passed H. R. 3005, the extension of the regular draft act with an amendment which extended the Doctors Draft Act for 2 years.

This bill was passed on June 17, 1 month after I had appeared before the Rules Committee to request a rule on a separate bill to extend the Doctors Draft Act. On Monday, June 20, I asked unanimous consent to take from the Speaker's desk H. R. 3005, disagree to the Senate amendments, and agree to the conference requested by the Senate. This was granted, and thereafter we held a full and free conference with the Senate on June 21, and as a result filed a conference report in the House.

Now let us see what the conference report provides.

It extends the regular draft act for 4 years until July 1, 1959.

It also extends the Dependents Assistance Act for 4 years until July 1, 1959.

And it makes some changes in the existing draft act.

As you know, under the law young men can enlist in the National Guard prior to attaining the age of 18½. They are deferred from induction so long as they participate in the National Guard. But remember that under the present law, anybody deferred for any reason remains liable up to age 35. And this applies to National Guard men and any other person who gets a deferment. So the House bill provided that these individuals would not remain liable after they passed the age of 26.

The Senate bill accepted this principle of a reduction in the age of liability, but raised the age to 28.

Now the next question involved the amount of prior service necessary to qualify for exemption as a veteran under the draft law.

The conferees agreed that if a person was discharged with 12 months of service, or 6 months of service if discharged for the convenience of the Government, he would be classified as a veteran.

The Senate amendment provided a new exemption for persons who served on active duty for a period of not less than 18 months in the Armed Forces of a nation in which the United States is associated in mutual-defense activities so long as that country grants reciprocal privileges to American citizens residing in such foreign countries. Since the House passed a similar proposal last year, we agreed to the Senate amendment.

To sum up, let's see what kind of a draft law we will have after the conference report becomes law.

First. All young men attaining the age of 18 will still be required to register.

Second. They will not be liable for induction until they reach the age of 18½ and even then they can't be inducted if there is any person registered in their local board who is available and is over the age of 19. Today they are drafting men at the age of 21.

Third. Young men will still be deferred to complete high school or go to college.

Fourth. The exemptions will remain the same.

Fifth. Young men will still be able to appeal their classifications. The appeal processes remain the same.

Sixth. Young men will still be able to join the National Guard prior to attaining the age of 18½ and will be deferred from the draft so long as they satisfactorily serve in the National Guard up to the age of 28.

Seventh. Any man discharged for the convenience of the Government after serving 6 months on active duty will be considered a veteran and will be exempt from induction except in time of war or national emergency. All others discharged after completing 12 months or more of active service will be considered a veteran and will be exempt from induction except in time of war or national emergency.

Now that's the picture of how the new draft law will operate.

That brings us to the Doctors Draft Act which was added as a separate title by the Senate to the bill that extended the regular draft act.

The House Armed Services Committee reported a doctors draft bill to the House last May 10, as I have already mentioned. We appeared before the Rules Committee on May 17 for a rule. In the meantime, I discussed the matter with many Members of the House and with officials from the Department of Defense to determine whether we could possibly reduce the draft age of doctors, and had considerable correspondence with the chairman of the Rules Committee.

After going over the figures carefully with representatives of the Department of Defense; after carefully studying the testimony; and after going over the statistics with people from Selective Service, I asked the Armed Services Committee to authorize me to offer an amendment to the bill which we had reported to the House to reduce the age from 51 to 45 insofar as physicians and dentists are concerned.

The committee agreed to such an amendment.

Mr. Speaker, I have just as much respect for the medical and dental professions as anyone else. None of us like the necessity of drafting doctors, but we all know that the health of the armed services comes first.

We know that we cannot in good conscience extend a law to draft the young men of our Nation without assuring them the best possible medical care and that is the sole purpose of extending the law.

The Senate conferees were insistent that the age of liability for physicians and dentists remain at 51 as it is today.

We agreed upon a draft age of 46. No physician or dentist may be drafted under the doctors draft law after he attains the age of 46.

In other words, the Senate conferees agreed to come down 5 years from the present law.

Now let me give you the reasoning behind the draft age of 46.

There are just so many physicians in this country who are liable for service who will be graduating from medical schools and will complete their internships within the next 2 years.

In fact, there are only 6,691 physicians in this category.

Now the requirements for the uniformed services for the next 2 years amounts to 7,771, so if we took every single available medical school graduate during the next 2 years we would still be short 1,152 from our requirements.

But, in addition, we have got to think about the future.

If we take all our available medical school graduates for the next 2 years, then we will have no source of experienced physicians to call upon who will be liable under the regular draft act 2 years from now when the doctors draft law expires.

Some 1,800 of our available medical school graduates will be deferred to take residency training so that they can become specialists or more experienced physicians.

Now we suggested to the Senate conferees that we take all of the medical school graduates and not defer any one for residency training. When we did this we fully realized that in offering that suggestion we were creating a problem for ourselves that might be insurmountable 2 years from now.

The Senate conferees refused to go below a draft age of 46. They said that a draft age below 46 would not assure the ned services of experienced physicians and specialists after : doctors draft law expires. We knew this was true.

They said that if we take all of the medical school graduates ring the next 2 years and just a hand full of special registrants, will have a medical service in the Armed Forces made up ›stly of young men who have just completed their internships. other words, most of the doctors treating our servicemen ›uld be young, inexperienced doctors. We knew this would be : fact.

And finally, the Senate conferees said that if we limited the aft age for physicians to a point where it is barely able to ovide physicians even by taking all of the medical school aduates for the next 2 years and deferring none, that we ›uld be in serious difficulty particularly if there was any in- :ase whatsoever in the size of our Armed Forces in the next years.

We know how unsettled world conditions are and that no .e can say with certainty what the size of our Armed Forces ll be in the future. Last week's incident in shooting down a avy plane in the Bering Sea is evidence of unsettled conditions at daily confront us.

Now a draft age of 46 will give us enough physicians to fill : requirements of the uniformed services for the next 2 years d at the same time will permit us to defer enough medical hool graduates so there will be an adequate source of experi- ced physicians available still within the draft age 2 years from w when the doctors draft law expires.

Bear in mind that any person deferred for any reason since ne 19, 1951, remains liable up to age 35 under the regular aft law. This is the way we will get physicians 2 years from ›w when the doctors draft law expires.

The Senate did agree to a provision which was contained in : bill we reported to the House that any physician or dentist ıo applied for a commission at any time in the medical or ntal corps and who was rejected for physical reasons would ıt be liable under the doctors draft law after attaining the age 35. This means that if a man tried to obtain a commission the medical corps of the Army, for example, and was rejected r physical reasons and he is now 35 years of age, he is no nger liable under the doctors draft law.

Now it has been argued by some that there would be no need r a doctors draft law if we stopped treating dependents of rvice personnel and others who are entitled to medical care ›m service doctors in accordance with law.

Let us analyze this and see what the facts are.

Under the law medical care is authorized for civil service ıployees, foreign service employees, employees of the Bureau Indian Affairs, certain nationals of foreign governments, sea- en, and certain beneficiaries of the Veterans' Administration.

And in addition to that, medical care is authorized for the :pendents of service personnel.

These authorizations are based upon law. But let us see if ese laws are being abused.

In 1954 the beds occupied by patients in hospitals and in- :maries under the jurisdiction of the Department of Defense /eraged 48,000 daily. Of this number, only 2,400 were not :rvice personnel, retired personnel, or dependents of service :rsonnel.

Of this 2,400, practically all, with the exception of veterans, ere serving outside the continental limits of the United States a civilian capacity or were employed by the Department of efense in a remote area of the United States where no civilian edical facilities are available.

Are we going to ask civilian employees to work overseas with .e Department of Defense and not assure them of an adequate merican standard of medical care?

Are we going to ask civilian employees of the Department of efense to work for the Federal Government in remote areas : the United States where the only doctors available are service ›ctors and refuse them the right to be treated by service ›ctors?

We have traditionally provided medical care for the dependents of service personnel and retired personnel.

I can think of nothing that would do more to destroy the morale of our Armed Forces than to deny the dependents of our service personnel medical care on a space and facilities available basis.

In other words, if the hospital is not there or the facility is not there, or it is overcrowded by service personnel, the dependent cannot receive treatment.

All of the dependents and service people know this.

But if there is space and if the facility is available, then these dependents are entitled by law to medical care. If the Congress wants to take away this privilege, it will have to be done by legislation.

Now widows and dependent children of deceased personnel of the Armed Forces are also entitled to medical care. But the actual number who benefit by this entitlement is a different matter.

The number of these people who occupy beds in hospitals and infirmaries is considerably less than 1 per cent of the total average occupied by patients in hospitals and infirmaries under the jurisdiction of the Department of Defense.

Our committee has gone into the matter very thoroughly. As a matter of fact, I asked the Department of Defense to give me an estimate as to the number of uniformed physicians who are considered to be devoting a major portion of their duties to the treatment of individuals other than Armed Forces personnel and dependents of armed services personnel.

I was advised that if all medical care were abolished for all personnel now entitled to medical care from the armed services other than armed services personnel and their dependents we would only be able to eliminate about 40 uniformed physicians throughout the entire Armed Forces. That is veterans, civil-service employees, foreign-service employees, seamen, foreign nationals, and employees of the Bureau of Indian Affairs.

If we abolished all dependent medical care for the members of the armed services in the United States, we would only be able to reduce the number of uniformed physicians in our armed services by approximately 581.

I want to emphasize this point:

If we abolished all dependent medical care in the United States and all medical care for all civil-service employees and veterans who are admitted to the service hospitals in the United States and overseas, we would only reduce the call of uniformed physicians for our armed services by 621 physicians.

Now some of you may ask, Why do we not use more civilian physicians?

Well, the armed services do employ 311 civilian physicians in industrial dispensaries, ordnance depots, and places of that nature. There is no limitation on the number of physicians that may be employed by the Department of Defense—but a practical limitation is contained in the inability of the armed services to hire civilians under existing civil-service wage scales. It is a little difficult to compete with the net income of the average physician which is now in the neighborhood of $15,000 annually.

Now someone might say, Well we wouldn't have to take these older physicians if we took the younger doctors who have already served in the Armed Forces.

I am not going to support any program that requires us to force a doctor who is a veteran under the law to serve his country twice when there are many doctors in this country who are under the age of 46 who have never served a day in their life. The doctors who are coming in during the next 2 years will be doctors who have never served on active duty, and they are now in Priority III.

Mr. Speaker, we have looked at this proposition from every angle. And distasteful as it may be, discriminatory as it may be, disturbing as it may be, inconvenient to the doctors as it may be, nevertheless the servicemen of our Nation are entitled to the best medical care we can provide. They will not get it unless you pass this conference report.

We cannot have adequate national security without proper medical care, and the only way we are going to get proper medical care for the next 2 years is by extending the Doctors Draft Act for 2 years.

Two years from now there should be enough physicians graduating from medical school who are nonveterans, plus those who have been deferred to take specialty and residency training to meet the needs of the Armed Forces if the strength of the Armed Forces stands where it is today.

For the next 2 years, there is no other solution to this problem but to pass this conference report extending the doctors draft law for 2 years.

The law I am asking you to extend gives the President the authority and the discretion to issue special calls under such regulations as he may prescribe as to how many doctors will be called to meet the needs of the services.

Now let me get this point across. The doctors draft law is an authorization law. If the facts change and no longer warrant its implementation, then the President has the authority to modify or change the calls to meet the conditions as they arise.

I have confidence in the President to administer this law in such a manner as to avoid arbitrary calls on physicians and dentists, and at the same time to assure the armed services adequate medical care.

The issue here is simple.

We either pass this conference report and assure an adequate source of medical and dental personnel for our Armed Forces and inconvenience some physicians and dentists who have never served a day of active duty in their life, or we let the convenience of a few physicians and dentists jeopardize the health of our armed services and the national security.

I have received telegrams from every dental and medical society in the United States, as I am sure every one of you have. They all oppose the draft law for doctors.

Not a single one of them, however, can assure the Armed Forces of an adequate source of physicians and dentists without the doctors draft law.

And as far as I am concerned, when it comes to a choice between the health of our Armed Forces and the desires of the American Medical Association and the American Dental Association, I shall elect to assure the members of our Armed Forces that they will receive the best possible medical and dental care.

We either vote to give to the men we draft or the men who volunteer the best in medical care, or we bow to the dictates of the American Medical Association.

I have before me a telegram from the American Medical Association urging that this conference report be recommitted.

Now what will you accomplish if you recommit this conference report.

Today is the 28th of June. These four important laws, the very props of the defense of the Nation, expire on midnight June 30—60 hours from now.

What would be the consequence if this conference report is recommitted and no agreement can be reached?

Everything stops on midnight June 30. The draft stops; the dependent wives and children will have their checks stopped and the whole machinery of these four main props of the defense of the Nation will be brought to a halt.

In a letter from General Hershey, dated June 24, he said:

> It is estimated that, should the Congress fail to extend the induction authority prior to July 1, 1955, at least 50 percent of the 10,000 men already called for induction in July would be affected to the extent that their orders for induction would have to be canceled.
>
> With respect to the effect of a failure to extend the so-called Doctors' Draft Act prior to its scheduled termination date on July 1, 1955, it should be pointed out that immediately upon termination of this act all actions of the Selective Service System with respect to classification and selection of physicians and dentists would be rendered void.

I ask you not to jeopardize the security of the Nation in such a manner.

Mr. Miller of Nebraska. Mr. Speaker, will the gentleman yield for a question? I wanted to ask the gentleman a question about the ratio of physicians in the Army including the dependents that they take care of as compared with the civilian population. Can the gentleman give us any information on that?

Mr. Vinson. I do not have that information.

Mr. Miller of Nebraska. I understand that the ratio is about 4 physicians to 1,000 in the Army, and in the civilian population the ratio is 1 to 1,200 people in the United States.

Mr. Jonas. I want to ask the gentleman about the acti
the other body in striking out an amendment I proposed c
floor and which was agreed to on the floor at the time th
was originally passed by the House.

Mr. Vinson. That is the provision with reference to a
who had been before the Board and rejected because of a
cal disability. He cannot be called back. That is in the conf
report. A man who has been passed on and to whom a
mission has been refused because of a physical disability.
is the end of it—he cannot be called back.

Mr. Kilday. Mr. Speaker, if the gentleman will yiel
gentleman from Georgia, of course, has correctly stat
provision with reference to doctors who have previousl
denied a commission on account of physical disability,
believe the gentleman from North Carolina [Mr. Jon
referring to the amendment adopted on the floor.

Mr. Jonas. That is correct. The amendment proposed
and which the House adopted.

Mr. Kilday. That is the regular draft extension whic
adopted by the House under which a man who had been r
at an induction station could not be called back.

Mr. Jonas. That is correct. The amendment was put
bill on the floor and provided that if a registrant sho

disability, his liability for service would expire at the age
Why did the conferees agree to the elimination of that pr
after the House, following considerable debate and th
consideration, affirmatively approved it?

Mr. Kilday. Mr. Speaker, if the gentleman will yiel
particular provision is not in this bill. The conferees of th
body were adamant in their opposition notwithstanding t
sincere effort to retain the provision because it was a pr
put in on the floor of the House. We did not prevail
and that is not in this bill.

Mr. McCormack. I congratulate the gentleman from
on the able and powerful speech he has made. It is a
which should convince the great majority of the member
the House, and I join with the gentleman from Geo
urging that the conference report be agreed to.

Mr. Dixon. Mr. Speaker, during the hearings on the ex
of the draft law in the Senate the junior Senator from
Wallace F. Bennett, indicated that, if necessary, he wou
pose an amendment to section 16 (g) of the Universal
Training and Service Act, as amended, for the purpose of
ing the exempt status of those persons called to serve as m
of the Church of Jesus Christ of Latter-day Saints—Mor
assigned to serve in the missions of the church.

The problem to which he sought solution has arisen
some local boards and State administrators have failed to
nize the IV-D status of these ministers—despite the fact t
National Director of Selective Service has always consider
the young men of this church, who are ordained as m
and assigned to serve in the missions of the church, were
the definition of ministers of religion as defined in section
of the act. In those instances where the local and State
have failed to recognize the true status of these minist
Director has had to rely on appeal procedure in order
the proper classification.

After hearing Senator Bennett's explanation of the pr
and General Hershey's testimony to the effect that he
ways regarded these ministers as included in the definit
section 16 (g), the Senate Armed Services Committee con
that the amendment proposed by Senator Bennett w
necessary.

The committee made the following report of the pr

> Exemption of ministers of the Church of Latter-day Saints (Mo
> The junior Senator from Utah, Hon. Wallace F. Bennett, a
> before the committee in connection with a possible amendment to
> 16 (g) (1) of the Universal Military Training and Service Act to spe
> insure the exemption of those persons called as ordained ministers
> Church of Jesus Christ of Latter-day Saints (Mormon) and assig
> serve in the missions of the church. Assurance given in writing

tor of Selective Service to the Senator from Utah reflected that such
dment was unnecessary inasmuch as Selective Service considers that
individuals are already entitled to IV-D classification under existing
The letter referred to and a letter from the Assistant Secretary of
ise for Manpower and Personnel appear in the printed hearings.

his report, coupled with Senator Russell's statement in the
ord of June 16, 1955, to the effect that the committee ex-
sly considers any clarifying amendment unnecessary inas-
h as these ministers are in fact already entitled to IV-D
is under existing law clearly defines the position of our col-
ues in the Senate.

should like to ask the distinguished chairman of the House
ied Service Committee if he and his committee share that
iion in the light of General Hershey's testimony and the con-
atory comments of the Senate committee?

R. VINSON. Mr. Speaker, let me say to the gentleman from
that I concur completely with the report of the Senate
ied Services Committee and Senator Russell's statement that
larifying amendments are needed to the Universal Military
ning and Service Act with regard to the exemption of minis-
of the Church of the Latter Day Saints. It is my understand-
hat these young men are exempt so long as they are ordained
isters and assigned to serve in the missions of the church.
soon as they have completed their work in the missions,
h I understand is 2½ years, the exemptions then cease and
become subject to induction like·all other individuals.

R. SMITH of Virginia. Mr. Speaker, I always hesitate to
issue with the distinguished gentleman from Georgia, my
close and dear friend [Mr. Vincent]. I do not think any
has lived in our generation who has done more for national
nse than the distinguished chairman of that committee, the
leman from Georgia [Mr. Vinson], and I want to take this
rtunity to compliment him on the great service he has
ered to the country.

nfortunately, he is human. All human beings sometimes
e mistakes, and this time it [sic] when he made a bloomer.•It
shame that the House is not permitted to have an oppor-
ty to know what this is all about, but here the House has
deprived of an opportunity to discuss the doctors' draft
eason of this parliamentary maneuver which took place in
her body. The gentleman says that the Committee on Rules
not give them a rule. It is true he came before the Com-
ee on Rules. We were so unconvinced, and so thoroughly
inced that it was wrong, that no rule was granted, and the
ter lay there for some time. Finally, I fixed a date on a
rsday for the final hearing on that bill. The day before the
hearing this little maneuvering went on, and the bill was
ted as a rider to the regular draft bill in another body.
n the chairman advised me that he did not want a rule, so
ule was granted.

hat bill is on the calendar, and if it came to the floor we
ld have an opportunity to find out whether it was right or
ng. But I am going to tell you in the few minutes allotted
and I am sorry it is not more, just what is the matter with
s far as I have had time to see it.

n the first place, it is a thoroughly discriminatory bill. No
r class of citizens in the United States is discriminated
inst and drafted into service simply because of their vocation
ife. I expect I have done more than most members of the
nmittee on Armed Services, because I have read every page
he hearings and I know what I am talking about. There is
ieed for a doctors draft. The evidence in these hearings shows
there is no need for it. It is admitted that there are ample
luates coming out of the medical schools to fill every need.
Health Resources Advisory Committee from the Defense
artment which deals with this subject notified the American
lical Association in December of last year that the doctors
t was not needed and would not be asked for. Subsequently
came in and asked for it. The only reason they could give
changing their minds was that they wanted to defer 1,000
he young doctors for further training and take in old doctors.
t was the only reason. If they would use the young doctors
are coming out of the schools there would be no need for
draft, and the evidence quite clearly shows it.

During the Korean war when people were getting killed and wounded the Army got along fine with 1.6 doctors per thousand. Today, in time of peace, they are asking you for 2 doctors per thousand, more than they used in time of war.

Why do we have this need in peacetime? Here are five reasons:

First. They are treating 1,100,000 civilian employees of the Defense Department.

Second. They are treating all dependents of servicemen.

Third. All retired personnel and dependents.

Fourth. All the personnel of the foreign Embassies.

Fifth. All wards of the Bureau of Indian Affairs.

There will be a motion to recommit this conference report. I am not permitted, under the rules of the House, because I happen to be on the majority side, to make that motion, but I would if I could make a motion to recommit with instructions to strike out the doctors draft, but I am not permitted to do so. My astute friend wants to choke this thing down your throats without ever giving you an opportunity to know what you are doing, or to vote on the direct issue.

Do you know you are drafting American citizens here to treat the personnel of foreign embassies in this country? I asked the chairman of the committee when he was before the Rules Committee: "Do you think it is the right American thing to do to draft an American citizen doctor 46 years old to treat the cook of the Russian Embassy?" That is what you are doing.

Sometimes there are questions of principle; this is a question of principle. I do not care about the doctors, but I do care about the vicious principle involved in this bill.

You are drafting, in the fifth place, doctors to treat all the Indians, the wards of the Bureau of Indian Affairs. Did you know that? How many of the Members knew it? But after all that, since the time the Army notified the American Medical Association that they would not ask for the draft of doctors, since that time it has been decided to reduce the Army by 450,000 men, yet they are still asking for a greater proportion of doctors than they did in the heat of hot war.

Mr. Speaker, are we going to stand for this? Are you going to stand here and push this thing down the throats of American citizens and not voice your protest?

This bunk about its going back to the conference committee and not having a draft bill, I want to say to you I voted for every draft bill that ever came before us. I was one of those who by one vote extended the draft 3 months before Pearl Harbor; so I am not any no-draft man, I voted for every draft bill.

When this bill goes back to conference it can be settled in 15 minutes, and we can bring the doctors draft bill to the floor of the House where we can do the right thing. If you vote for it, it is all right with me, but I insist, and I ask you to stand on the question of principle and not permit yourself to have your mouths closed and your opportunity for consideration denied to you by a parliamentary maneuver such as that with which we are confronted this afternoon.

Talking about these civilian employees of the Army, your drafted doctors in 1948 delivered 42,000 babies for personnel of various and sundry people of the armed services, 42,000 babies. All of that could have been done by civilian doctors under contract. In 1948 they delivered 42,000 babies, but in 1953 the doctors delivered 145,000 civilian babies. Is not that fine?

The answer to the problem is simple, and the chairman of the committee, my dear friend, the gentleman from Georgia [Mr. Vinson] told the War Department in these hearings:

> Now, by the 15th of May you come up here with a plan to treat these civilians through contact with local doctors.

Nothing was ever heard of that. Apparently the armed services simply ignored that demand.

In connection with the conference report, may I say that the House conferees fought valiantly to reduce the age limit. They tried to reduce it to 40; they tried it to 42. They fought valiantly for their position and just as valiantly surrendered and signed the conference report.

I am asking you to send this back. Let them get together over there, and let them do the right thing. Let us also put out a little warning that the House is not going to sit supinely by and have its prerogatives taken away from it and not be given the opportunity to consider a matter than involves as great a principle as anything that ever came before this body.

MR. JUDD. With respect to the motion to recommit, the gentleman said he would not be given that privilege because he is on the majority side. May I say that I tried as a member of the minority side to get the privilege of offering a motion to recommit with instructions to strike out title II. That would give the House a chance to vote on this issue by itself. But I was denied that privilege on my side. So there will be offered by someone else on this side a straight motion to recommit which I hope will pass because it is better than letting the conference report go through in its present form.

MR. DURHAM. Mr. Speaker, I hope, too, that this measure will be sent back to the conferees.

I realize that we have serious considerations at stake, since the Universal Military Training and Service Act expires on June 30. This circumstance, however, is not the fault of this body, since the House passed the bill extending the draft on February 28, with no thought of including the doctors draft extension in the basic draft legislation. Now, the present difficulty arises because the Senate saw fit to tack on to the draft bill a new title, not previously considered by the House, effecting the extension of the Doctors Draft Act and other related matters.

I am definitely opposed to such a legislative procedure. The doctors draft legislation is a highly important and controversial matter, which affects the welfare and health of the entire population of the United States. This measure could have been considered in the House as a separate piece of legislation in the usual way and in ample time, had not the other body combined the two pieces of legislation.

The Doctors Draft Act was a necessity born of an emergency. I have been opposed to it all along because it is "class" legislation and as such is not the American way of doing things. I went along with its original enactment and subsequent extensions, however, because I felt it was necessary during the Korean crisis. Now we have reduced our Armed Forces and I seriously doubt the wisdom of continuing this legislation which we all frankly admit is discriminatory.

From the evidence produced at the hearings on the doctors draft extension, and from my examination and study of this whole subject, I am convinced that if the armed services utilized all the medical skills and personnel available, and effected a better distribution of physicians and skilled medical personnel, we would not need to enact this class legislation. I know personally of doctors now classified as surgeons who are being used for nothing more than bandaging surface wounds and administering cathartic pills. These ministrations could be carried out by trained and available personnel if proper organization and planning are brought to bear on the subject.

There is no question but that all of us want to take care of the health and welfare of our men in the armed services and their dependents, but I believe this can be adequately provided for in the basic draft law if applied to doctors and dentists as to all other persons, without again inflicting class legislation on a particular occupational group.

The conflicting testimony on the necessity for drafting doctors and dentists before both House and Senate committees poses some grave questions as to the advisability of continuing this draft of specialized personnel for 2 years longer.

Dr. Frank B. Berry, Assistant Secretary of Defense, Health and Medical, told the Senate committee that—

> We have today slightly more than half of the total number of medical officers authorized for the regular corps of the three services. * * * In addition we have only a handful of career medical and dental Reserve officers on active duty.

This last statement points up the urgent need for the Depar ment of Defense to formulate a determined program to attra and retain career medical personnel on a voluntary basis.

Earlier in the Senate hearings Dr. Reuben R. Chrisman J representing the American Medical Association, called attenti to the figure announced by the Secretary of Defense for t planned military strength of the country, this figure bei 2,900,000. By direction of the Secretary, the authorized phy cian ratio is 3 doctors per 1,000 troop strength, which wou call for 8,700 doctors. Dr. Chrisman pointed out, however, th in earlier hearings before the House committee, the physici strength was shown to be 10,360 as of March 31, 1955. Es mated losses during the next 2 fiscal years were shown to 7,424, leaving physicians on duty in the Armed Forces to t number of 2,936. Thus the number necessary to bring physici strength up to maximum authorization would be 5,764, althou the Department of Defense claims a requirement of 6,926 placement physicians, which includes 845 for the Public Hea Service. This number would provide a greater ratio than doctors per 1,000 troops, and the inclusion of 845 docto through draft, for Public Health Service raises a grave questi of propriety.

In the face of this testimony, there is the report of the Hea Resources Advisory Committee of the Office of Defense Mob zation in January, 1955, which states that if mobilization c tinues at presently announced levels, it will be possible to ma tain the present physician staffing ratios of the armed servi with the new graduates of medical schools who are liable service under the basic draft act.

The task force of the Hoover Commission is of this sa opinion. The task force also recommends that the doctors dr law not be extended and expressed the belief it was unfair principle and has in the past been abused in administration.

Testimony from the American Dental Association called tention to the conflicting estimates of the number of de officer replacements needed by the Armed Forces and affirn its belief that dental graduates subject to the draft could v effectively constitute the main source of dental officer repla ments, especially so if the present dental officer staffing patt is improved.

Serious questions have been raised in testimony before committee indicating the need for the Defense Departmen launch programs to attract to the services career physicians specialists on a voluntary basis, to obtain services of civil doctors in areas where they are available, to provide medi care for civilian employees and civilian dependents by o than drafted physicians, and related problems. The whole ject of how best to care for dependents of military perso needs also to be thoroughly explored with the possibility using civilian physicians and facilities wherever possible. In connection a questionnaire filled out by 1,600 physicians arated from the service during the first half of the year 195 reported by the AMA in its official journal on January 1955—shows that military doctors spent 61.6 per cent of t on their civilian patients. Of this amount of time, 28 per c went to dependents and 32 per cent to other civilians. This in the United States. Overseas the percentage was higher. M tary doctors overseas spent 72 per cent of time caring civilians, with 8.4 per cent of time going to civilian depende

Now, according to the AMA estimates, the total number doctors in the United States totals 221,000 in a population 165 million. This is a ratio of 1 doctor to every 747 civilia as contrasted to the ratio of 3 per 1,000 troop strength in t armed services. Also, the Department of Defense ratio do not take into consideration the interns in military hospitals a only considers one-half of the military residency physicians the grounds that they do not actually give medical care.

Mr. Speaker, in my opinion, the problems in the doctor's dra legislation are too large and too important to push this legi lation through as an afterthought and as a mere appendage the basic draft law. I urge that the bill be recommitted to th conferees for deletion of the title relating to the doctors draf

(Mr. Durham asked and was given permission to revise and tend his remarks.)

Mr. Judd. Mr. Speaker, I voted for the doctors' draft in ugust, 1950. We were at war. It was necessary to enlarge our rmed Forces on a crash basis, calling back into active service ns of thousands of men who had already fought for years in 'orld War II. The medical services had to be expanded in st as rapid and, to some extent, disorderly manner. Much as regretted having to vote for a measure which openly discrimiited against one group of our citizens, because of their profesonal skills in the healing arts, I was willing to swallow my nvictions with respect to the Constitution of the United States ıder those circumstances, for the very reasons presented by ıe gentleman from Georgia. But his reasons do not apply today. 'e are not at war today and have not been for 2 years. Our rmed Forces have been substantially reduced.

I would vote to extend the doctors' draft law now if it could demonstrated to be necessary to get enough doctors for the en in the Armed Forces. But that has not been and I think ınnot be demonstrated. So I cannot vote for title II of this onference report under the circumstances now prevailing.

First. The procedure under which this conference report is rought before us is wrong, as the gentleman from Virginia has well pointed out. We are asked to swallow here, without even ılping, a very controversial piece of legislation we have never ɜen permitted to consider, debate, and amend under the usual ıles and practices of the House of Representatives.

Even worse, the whole principle of discriminating against one oup of citizens is wrong—and certainly unjustifiable unless can be shown to be absolutely necessary. And that cannot be ıown. The Health Resources Advisory Commission of the ffice of Defense Management in January of this year said the octors' draft was not needed to get enough doctors.

The Hoover Commission Task Force on Federal Medical ervices, on February 19, of this year, specifically recommended ıat this piece of legislation, the doctors' draft law, not be exnded or reenacted. Those are its words.

Then why does the Pentagon say it is necessary? You know ıe reason. It is a lot easier to get doctors and dentists by force ıan by building up an attractive medical service that doctors ill be glad and proud to enter as a career. As long as the ilitary can get them by compulsion under a draft, they will ever build up again an adequate professional medical service.

The gentleman from Georgia asked, "How are you going to t doctors if you do not draft them?"

The answer is, "Get them the same way we get other spealized personnel—that is, provide a greater incentive."

What did we do when we could not get or keep enough ergeants and various types of specialized technicians in the rmed Forces? We passed a bill just a few months ago to make ıe positions more attractive. It is working.

We did not say, "We are going to draft you and make you end 3 more years in the Marines because we need expert techicians, expert mechanics, and expert electricians in order to ive our boys every proper service."

We did not go down to the filling stations and airplane angars and grab all the top mechanics up to 45 years of age, o guarantee that the boys whom we draft to fly our planes and lrive our tanks have the finest specialists to make sure their nachinery is in tiptop shape and their lives will not be endanered. Why not?

We do not go down to the Statler and the Mayflower Hotels nd say, "We are going to draft all your chefs under 45 because ur boys must have the very best nutrition possible." Why not?

Just why do we pick out one particular group of our citizens nd say that even in peacetime it has got to render a different ype and degree of service than any other group of citizens, and t a time when the agencies set up to study this very problem ay that it is not necessary?

Who should know more about it and give a more unbiased eport than the Office of Defense Mobilization and the Hoover ommission? They say this doctors' draft is no longer needed.

Interestingly enough, the Department of Defense reported that the number of available doctors under the regular draft during the next 2 years would be 6,200. Surgeon General Armstrong testified there would be 6,600. The Health Resources Advisory Committee of the Office of Defense Mobilization said there would be 7,000. Now, here are 3 agencies of the executive branch that ought to know most about the matter and they come up with 3 different figures. Apparently they do not have enough or sufficiently expert accountants. Maybe we ought to draft into the Armed Forces all the CPA's under 45 years of age, and see if they cannot determine what the correct figure is.

Another reason why the military say they do not have enough doctors is because they do not use them efficiently. Almost every doctor in the service will tell you that.

Another is that it uses them to treat 3 million dependents and more than 1 million civilian employees. That may be necessary overseas, but not in most American communities.

Another is that it details them for various civilian medical agencies like the Public Health Service. That is a wonderful organization doing a very important work. But since when is it our system to draft men in middle age for civilian jobs?

Why, then, does the Pentagon say the draft is needed? Because it can get its doctors this way easily. They have not taken the trouble to develop a really attractive career service. And if the House passes this bill today, I venture to predict that they will be here 2 years from now, and then 2 years from that time, asking for further extension. It is human nature never to do voluntarily the things necessary to correct a situation, as long as one can overcome it by the coersive [sic] power of the Government.

Mr. Speaker, I hope the motion to recommit will be adopted. Then we can tackle this problem and solve it in the regular American peacetime way. No one in the Armed Forces is going to suffer for lack of sufficiently trained and experienced doctors.

Mr. Vinson. Mr. Speaker, I yield 8 minutes to the gentleman from Missouri [Mr. Short].

Mr. Short. Mr. Speaker, I shall not take 8 minutes which the chairman of the committee has so generously allotted me.

We have got to face a reality more than a theory here today. It is pretty tough when you are caught between the millstones of two great, able, and fine gentlemen like the gentleman from Georgia, the chairman of the committee, and the gentleman from Virginia [Mr. Smith], the chairman of the Committee on Rules. It only goes to show that there can be an honest difference of opinion between wise and good men on a highly controversial issue.

None of us wanted to vote for the doctors draft law when we originally passed it. We frankly admitted that it was discriminatory. But how in the world are you going to draft the youth of this Nation into the different branches of our armed services without providing adequate and well-trained and highly qualified medical care for them?

The gentleman from Virginia [Mr. Smith] says that the doctors in our Military Establishment have delivered 45,000 babies. Well, I am glad that the population goes on. I do not know how you are going to control human nature, which is a powerful thing, by passing a bill on the floor of this House. And who wants to stop all the fun?

I cannot understand why anyone would vote for the extension of the general draft bill for 4 years and extend the dependency benefits, which we do in this bill, and which is absolutely necessary for our national security, and then refuse to vote not only for an adequate number of doctors, but doctors who are trained and well-qualified. Our armed services must have some experienced doctors and not all neophytes.

I want to point out to the House here that in conference the Senate was very adamant on this particular point. They pointed out that even if all the young graduates of our medical schools were taken in the Armed Forces we would still be 1,152 short of the required number; but that we could go from 51 down to 46 years of age and still defer perhaps about 1,200 doctors who could take their 2 years of residency.

What Member of this House would want his son or daughter in the service, regardless what branch of service, to be treated, or to be operated upon by a youngster just out of medical school, until he has had at least 1 year internship and 2 years of residency? Members of our armed services even in times of peace perform hazardous duties and in times of war face the gravest dangers. They suffer violent shock, the severest wounds, and the most intense pain. Who is there among us who would deny them the best—the very best—of medical care? We should insist upon quality as well as quantity of physicians. It is a mathematical problem. It is not difficult for anyone to compute. If you go below the age of 46 you will have such a narrow margin that practically all the men in our armed services will have to be treated by rather young and inexperienced physicians.

I might say that as a national policy the services have drafted doctors not older than 38 years of age, but we all know as a matter of practical, commonsense you must have older doctors sandwiched in with these new recruits or graduates out of our medical schools if you are going to protect the health and maintain the morale of our armed services.

I think the doctors by and large are fairly well satisfied. They are patriots. Of course, they do not like it. You can understand that. But there are only a few doctors who have been bitter in their criticism so far as I know. I have had two or three call on me. But when you realize that the vast majority of doctors that will be brought in under this extension of the act for 2 years are men who have never served a day in the armed services, I do not see what justification there is for much complaint about it. Some of these doctors got their education at Government expense and I do not want to recall doctors with prior service. It is just about as simple as that.

There are very few changes in these bills except we did lower the age of the men who enlisted before their 18½ birthday in he National Guard, liable under present law for call to duty p to 35 years of age. The House lowered that to 26, the Senate extended the age to 28. We have agreed to the Senate provision. I think it is an improvement in the present general draft law.

In the doctors draft law, we voted not only to lower the limit by 5 years, from 51 to 46, which will allow many doctors to escape service, but we will get a sufficient number so that these doctors that are brought in will be not only graduates of medical schools but will have had their residency training. I repeat we want quality as well as quantity and the best is none too good.

Mr. Gavin. May I indulge your patience at this particular point. I would like to read from the statement that Rear Adm. Lamont Pugh of the United States Navy, former surgeon general of the Navy and now retired, made before this committee I think in 1953, which indicates why the doctors draft legislation is necessary:

> In December of 1948 the American Medical Association addressed a letter to each of 7,610 doctors in the United States who were then less than 26 years of age urging them to volunteer for active duty. Special reference was made to those who had received V-12 or ASTP training. The letters pointed out their liability for induction under the Selective Service Act which had been passed earlier that year and gave other pertinent information regarding the situation. Cards were enclosed for the recipient to fill out and return to the AMA, which in turn forwarded the cards to the Surgeon General of the appropriate armed service. The Bureau of Medicine and Surgery addressed a letter to each of the doctors from whom a card was received, giving complete information on how and where to apply for a commission and active duty. For those not holding commissions in the Medical Corps Reserve, the Bureau of Medicine and Surgery prepared an application letter, including a franked envelope addressed to the nearest office of naval officer procurement so that all that was necessary on their part to obtain the application forms was to affix their signature and mail the letter. A copy of the Bureau letter to each of these young doctors was also sent to our district medical officers and the appropriate officer-in-charge of naval officer procurement in order that they might contact each doctor and assist him in every possible way. Only 33 medical officers out of the total of 7,610 receiving the letter came on active duty for a period of 2 years as a result of this program.

Mr. Short. That is very true. But it does not reveal the true feelings of the doctors of America. They are fine men.

Let me say this in closing: Your conferees fought hard and diligently with the conferees of the other body trying to maintain every one of the positions of the House, but you know that all legislation is the result of compromise. We had to give as well as take. Those gentlemen over there were adamant. Both these laws are going to expire just 60 hours from now, on midnight Thursday. This administration, the White House, the Department of Defense, are very eager to have this conference report adopted today. I hope the House will go along with us, because we did succeed in persuading the Senate to lower the age from 51 to 46 for doctors.

Mr. August H. Andresen. The gentleman has referred to reducing the age limit in the regular draft from 35 to 28. What is the status of a man now who has already reached the age of 28? Will he be drafted under the new law if he is in class 1-A?

Mr. Short. If he is in class 1-A, he could be drafted under the law as it is today.

Mr. August H. Andresen. But after the present law expires on June 30, does he come under the new law then, so that if he has reached the age of 28 he will not be drafted?

Mr. Short. I doubt if they can draft anyone after that.

Mr. Martin. I would like to ask the gentleman from Missouri if it is not true that the President and the administration is very much opposed to the motion to recommit this conference report and are anxious to have this legislation passed because they know how pressing time is.

Mr. Short. Of course, it is as I stated. We are faced with a reality and not a theory. I rather deplore the fact that we did not have a full and open discussion of the extension of the doctors' draft as well as of the general draft law, but we did not have, although our committee reported out both bills weeks ago. Unless we act today, we imperil the safety of this Nation.

Mr. Madden. Mr. Speaker, it is indeed unfortunate that this legislation which includes the complicated and involved doctors-draft bill, comes before the House through the back door. The chairman of the Armed Services Committee and several Members appeared before the Rules Committee some time ago in order to get a rule dealing with the doctors draft legislation. For some reason which is not clear, the chairman of the Armed Services Committee and members of the conference committee saw fit to attach the complicated doctors-draft legislation to the extension of the original draft bill after it passed the other body. As a consequence, 435 Members of the House are barred from debating, speaking, and amending the doctors-draft legislation because it comes in here under the limited 1-hour debate allotted to a conference report.

There is no question that the doctors-draft legislation is class legislation and it involves the welfare and families of thousands of doctors throughout the country. It also indirectly affects thousands of families in regard to their medical attention and services. Every Member of Congress should be given an opportunity to express himself if he so desires, to offer and to vote on amendments to legislation of this importance. Under the present back-door approach which the conferees have seen fit to use in order to carry out the recommendations of the Pentagon, I am compelled to vote to recommit this draft legislation with the recommendation that the doctors-draft amendment thereto be brought back to the floor as a separate piece of legislation.

I voted for the doctors draft in 1950 when we were in active war in Korea and voted for the extension on two different occasions. This is the first time Congress has been asked to consider the drafting of doctors or any other professional or classified segment of our economy in times of peace. There has been a lapse of 5 years since the original doctors-draft law was passed and today it calls for a more complete study involving change and improvement. A great deal of testimony was presented to the Armed Services Committee, setting out that the doctors-draft law is not necessary at this time. We do know that the present policy of the administration has been to curtail and shrink our Army personnel, but in spite of this decrease, the present medical-draft bill calls for more doctors in the military than during wartime.

I am very much in favor of every member of the military and his family securing all the necessary medical attention to which he is entitled, by reason of his patriotic service, and I will gladly vote for any draft legislation that is essential for our military and for our defense. Considering the steamroller tactics used in ramming through the House this important medical-draft legislation as an appendage to the extension of the original draft bill, it is not fair to the public, the Members of the House, or the medical profession of the Nation. Therefore, I shall vote to recommit this bill with instructions that the doctors-draft legislation be returned to the House where it can be amply debated, amended, and passed in fairness to all concerned.

MR. JUDD. Accepting the argument that we must not draft boys into the armed services without giving them the very best medical care, does the gentleman think it is proper and constitutional to draft 845 physicians supposedly into the armed services to take care of our soldiers, and then detail them to work in a civilian agency—the Public Health Service and the National Institute of Health?

MR. KILDAY. Mr. Speaker, history has a way of repeating itself. Sometimes it has an alarming and frightening way of repeating itself. Those of us who were here in the summer of 1945 recall the letters we received within a matter of 2 or 3 days after V-J Day, "To get my boy out of the service." We remember that we helped to preside over not the demobilization of the finest fighting machine that was ever organized in the history of man—we did not see it demobilized—we saw it disintegrate before our eyes. Here we are talking about a draft in time of peace and we have it thrown out to us that we are attempting to draft doctors to treat the cook at the Russian Embassy. The Russians agreed to a meeting at the summit. Molotov traipses across the United States smiling—and we are willing to demobilize. For a period of more than 30 days the extension of the doctors' draft was stymied before the Committee on Rules. We have pending as unfinished business before the House a minimum Reserve plan which is caught in a parliamentary snarl—so much so that there has been reported out of the Committee on Armed Services today another minimum Reserve plan in the hope that we can break that parliamentary snarl. Instead of talking about the cook at the Russian Embassy, let us talk about the Russian MIG's off the coast of Alaska which 1 week ago tomorrow shot down in flames an American plane flying so close to American territory that it crash landed on the beach of an American island. The American people are willing to seize upon the prospect of one smiling Russian and ignore the American plane in flames because it is what they want to believe—that things are going to be all right.

There has been no argument here against the drafting of young men for service—the argument is whether we should extend the doctors draft to take in doctors who have not done any military service at all. These unorganized youths with no spokesmen are to be drafted. Then it is said that we can get the doctors under the regular draft. In every draft law that we have ever passed, we have placed a provision that no man shall be inducted until adequate housing and adequate medical care is available for him. Are we now going to say that we are going to take these young men into military service, go wherever the dictates of necessity may demand, and we are not going to carry out what we have done in the past to assure that they have the best of medical care available? Suppose you can get from the medical schools the number required, are you going to say that a young fellow who is out dealing with these horrible instruments of war, tanks, cannon, and guns, and whatnot, should his bones be broken in numerous places, that a man who has just completed his internship is going to doctor him, or are you going to say that he is going to have the best orthopedic surgeon that we can find at his disposal? This is just as simple and just as important as that. These are crucial times.

I have seen our Military Establishment go to pieces, but I hope not to see it again. I am sorry that a dispute has arisen between the chairmen of the two committees. I would have preferred to have discussed the doctors draft thoroughly on its merits. I would have agreed that the doctors draft is highly discriminatory and that it cannot be supported by reason and logic. It can only be supported because of the dire necessity that we must have the best of medical care when we draft the youth of the Nation and send them into service where they are subject to the dangers which exist.

Our laws have always provided for dependents of military personnel. It is traditional. We have all been alarmed in the recent past at our inability to retain career personnel, and we finally came to the conclusion that because we had been whittling away at the traditional benefits possessed by the military that we had lessened the attractiveness of a military career, and we have just begun to restore those traditional things when we are faced with this demand that they be eliminated.

How many doctors are assigned to all of these activities other than the military and veterans? Cooks for the Russian Embassy, if you please, and Government employees? A total of 40. A total of 40 are assigned to that type of duty. Eliminate them all and you have eliminated no part of the necessity of the extension of the Draft Act. Are you going to cut out the dependency care in an action such as this? I am in favor of providing an alternate program for taking care of the dependents. I propose to see to it that we get something done about it. Let us go to a group of doctors in the United States who know more about this subject than any other doctors in the United States. They were represented before our committee and the testimony appears at page 2674, Dr. William B. Walsh. He said:

> I appear here today as president of the National Medical Veterans' Society. I extend my gratitude on their behalf for your courtesy at similar hearings 2 years ago and at the opportunity to once again appear before this committee.
>
> The National Medical Veterans' Society supports the extension of the doctor-draft law for another 2-year period. After much soul searching and the consideration of the needs put forth by the military, we have no alternative but to support this discriminatory legislation.

He then explains the alternative for taking care of these dependents. Dependents consume, as the chairman has said, 800 of the total military personnel; the vast majority of these doctors are required for the active-duty military personnel. We must extend the draft notwithstanding the smiling Molotov in Chicago and San Francisco. We dare not send the President of these United States to a summit conference with it known throughout the length and the breadth of the world that the Congress of the United States has weakened in its support of the military program of the United States. Are we going to send him to a conference at the summit with it known by others participating in that conference that he can get so basic a thing as adequate medical care only through the greatest of effort and the bitterest of debate.

These things have plagued our Nation from the very beginning. Washington had them, so did Andy Jackson prior to the Battle of New Orleans; and again they plagued both sides after the first Battle of Bull Run, or the Battle of Manassas. And just before the Battle of Trenton, Thomas Paine wrote:

> These are the times that try men's souls. The summer soldier and the sunshine patriot will, in this crisis, shrink from the service of their country; but he that stands it now deserves the love and thanks of man and woman.

That is where we stand here now when we are not in a shooting war and when we want to prevent a shooting war.

Let us not be summer soldiers and sunshine patriots; let us adopt this conference report right now.

MR. MILLER of Nebraska. Under the rule the motion to recommit is subject to amendment, and I have an amendment.

THE SPEAKER. The gentleman from Georgia has moved the previous question on the motion to recommit. If the motion for the previous question is voted down the Chair will then recognize the gentleman from Nebraska to offer his amendment to the motion.

The question is on ordering the previous question.

The question was taken and on a division (demanded by Mr. Miller of Nebraska) there were—ayes 158, noes 80.

MR. JUDD. Mr. Speaker, I demand the yeas and nays on the motion ordering the previous question.

The yeas and nays were refused.

So the previous question was ordered.

THE SPEAKER. The question is on the motion to recommit.

MR. JUDD. Mr. Speaker, on that I demand the yeas and nays.

The yeas and nays were ordered.

The question was taken; and there were—yeas 171, nays 221, not voting 42, as follows:

So the motion to recommit was rejected.

The Clerk announced the following pairs:

On this vote:

Mr. Moulder for, with Mr. Mack of Illinois against.
Mr. McGregor for, with Mr. Buckley against.

General pairs:

Mr. Morrison with Mrs. St. George.
Mr. Polk with Mr. Simpson of Pennsylvania.
Mr. Eberharter with Mr. Jackson.
Mr. Dingell with Mr. Holt.
Mr. Quigley with Mr. Horan.
Mr. Chatham with Mr. Scherer.
Mr. Green of Pennsylvania with Mr. Ellsworth.
Mr. Gray with Mr. Gubser.
Mr. Rivers with Mr. Henderson.
Mr. Boykin with Mr. Kearns.
Mrs. Knutson with Mr. James.
Mr. Doyle with Mr. Knox.
Mr. Davis of Tennessee with Mr. Frelinghuysen.

Mr. Baker changed his vote from "yea" to "nay."

Mr. Mollohan changed his vote from "nay" to "yea."

The result of the vote was announced as above recorded.

THE SPEAKER. The question is on the conference report.

MR. VINSON. Mr. Speaker, on that I ask for the yeas and nay

The yeas and nays were ordered.

The question was taken, and there were—yeas 388, nays 5, answered "present" 1, not voting 40, as follows:

[Roll No. 100]

So the conference report was agreed to.

The Clerk announced the following pairs:

On this vote:

Mr. Mack of Illinois for, with Mr. McGregor against.

General pairs:

Mr. Morrison with Mr. Simpson of Pennsylvania.
Mr. Doyle with Mr. Scherer.
Mr. Moulder with Mrs. St. George.
Mr. Buckley with Mr. Frelinghuysen.
Mr. Green of Pennsylvania with Mr. Ellsworth.
Mr. Chatham with Mr. Horan.
Mr. Boykin with Mr. Holt.
Mr. Rivers with Mr. Jackson.
Mr. Polk with Mr. James.
Mr. Passman with Mr. Knox.
Mr. Eberharter with Mr. Kearney.
Mr. Quigley with Mr. Kearns.
Mr. Dingell with Mr. Henderson.
Mr. Davis of Tennessee with Mr. Gamble.
Mr. Sheppard with Mr. Gubser.
Mrs. Knutson with Mr. Canfield.

Mr. Barrett changed his vote from "nay" to "yea."

Mr. Christopher changed his vote from "yea" to "present."

The result of the vote was announced as above recorded.

A motion to reconsider was laid on the table.

MEDICAL FILM REVIEWS

Abdominal Pregnancy with Living Baby: 16 mm., color, sound, showing time 15 minutes. Prepared in 1954 by and procurable on loan from Milton L. McCall, M.D., 1542 Tulane Ave., New Orleans 12.

The purpose of this film is to depict an abdominal pregnancy with the delivery of a full-term infant and to demonstrate the procedures used in diagnosis. The patient had had four previous laparotomies, two for pelvic disease and two for intestinal obstruction. Partial intestinal obstruction was present during this pregnancy. The diagnostic procedures, including history, pelvic examination, abdominal x-rays, hysterosalpingography, and tocography, are shown and the relative importance of each one emphasized. Laparotomy with delivery of a living normal full-term infant is shown. The placenta attached to the "roof" of a frozen pelvis is visualized and is allowed to remain in situ. The abdomen is closed without drainage. The results of endocrine assays of chorionic gonadotrophins and follicle-stimulating hormone are charted, and the points important in the safe management of abdominal pregnancy are reiterated. In general, the surgical sequence is good. It is difficult to assimilate the information presented on the tocograph, mainly because the lettering is too small and the graph includes too many data to be read in a short period of time. The photography is excellent, and the film will be of interest, particularly for its teaching value. It is recommended for showing to general practitioners.

Lymphomas and Leukemias: 16 mm., color, sound, showing time 54 minutes. Prepared by Alfred Gellhorn, M.D., Edith Sproul, M.D., Ruth Guttman, M.D., Columbia University; and George Hyman, M.D., Francis field Hospital, New York. Produced in 1954 by and procurable on from American Cancer Society, 521 W. 57th St., New York 19.

This film is a Kinescope of a program that was originally presented by closed-circuit television. The emphasis is on the aspects of clinical and pathological diagnosis. The technique and use of bone marrow aspiration are presented. The indications for radiotherapy and chemotherapy are discussed, and appropriate case material is used to illustrate therapeutic regimens. This film offers a great deal of essentially valuable information on the subject of lymphomas and leukemias; however, there are a few relatively minor criticisms. One could criticize the discussion of lymphomas, including lymphosarcoma and Hodgkin's disease, as a whole, as if they were essentially identical entities. There is not enough emphasis on the individuality of these two conditions. A serious shortcoming is that no reference is made to the advisability of considering surgical removal of early lesions, which in the opinion of many authorities on the subject is definitely indicated and may be a significant factor in the prolongation of life. In the discussion of the therapy of lymphomas, as well as of leukemias, in their late stages, transfusion reactions are considered an unavoidable evil. No reference is made to the fact that in most instances these transfusion reactions can be avoided by the use of packed or resuspended red blood cells after removal of the plasma. In the experience of many investigators this procedure has eliminated all or at least most transfusion reactions. The color qualities of the gross pathological specimens demonstrated are very inferior, and some actually make the demonstration of these specimens completely valueless. The value of the presentation is reduced by the participants' speaking in monotones. In general, the picture is good and is suitable for medical society meetings and hospital staff conferences.

Tobacco and the Human Body: 16 mm., black and white, sound, showing time 15 minutes. Educational collaborators: C. A. Mills, M.D., University of Cincinnati and Klaus R. Unna, M.D., University of Illinois. Produced in 1953 by and procurable on rental ($2.50) or purchase ($62.50) from Encyclopaedia Britannica Films, Inc., 1150 Wilmette Ave., Wilmette, Ill.

This film is a report on the scientific results of modern research evaluating the effects of the use of tobacco. It analyzes the contents of tobacco smoke, demonstrates some of the physiological effects of smoking, and sums up the factors to be considered in deciding whether to smoke. This is an attractive, well-planned film, and the pictures showing laboratory activities are natural and plausible. In general, the part dealing with the innervation of the heart is very confusing, largely because the innervation of the heart and its interaction with the blood vessels are simply too complicated to dispose of in a few minutes. The narration and pictures relating to carbon monoxide are commendable for their clarity and moderation. Pictures of a rabbit's heart are somewhat confusing, since it is difficult to determine just when the slowing and speeding up of the heart are ascribed to the nicotine. The amount of nicotine needed to cause convulsions should also have been mentioned. In general, this film is recommended for showing to high school students with a good discussion leader.

Gait: 16 mm., color, sound, showing time 33 minutes. Produced in 1953 by the Imperial Chemical Industries Film Unit at the National Hospital, Queen Square, London, England, by Dr. E. A. Carmichael assisted by Miss R. M. Hern, F.C.S.P. Procurable on loan from Imperial Chemical Industries (New York) Ltd., Film Library, 521 Fifth Ave., New York 17.

This is an excellent film that explains in simple terms the mechanisms involved in various types of abnormality of gait and then demonstrates typical examples of such abnormalities. Explanations are clear, and the narrator has been careful to avoid complex terms. The narrator employs a colored diagram and a pointer to show the brain, spinal cord, peripheral nerve, and muscle; to demonstrate the nerve pathways and innervation of the muscle; and to point out and explain where various types of lesions occur. After an explanation of the location of a certain lesion, the gait of a person having such a lesion is demonstrated carefully. The selection of cases is excellent, and by good photography, including close-up views and views from beneath the patient, who is walking across a glass surface, every detail is well shown. Abnormalities of gait occurring in primary disease of the muscle, in lesions of peripheral nerves, in damage to the spinal cord, in disturbances of the pyramidal tract, in defects of sensation and in cerebellar disturbances, as well as certain additional abnormal movements, are demonstrated carefully. There is of necessity some lack of detail in demonstrating all the abnormalities occurring in the gait of a patient having poliomyelitis, but the major abnormalities have been well shown. As this presentation does not go into any great detail regarding gait training or the correction of abnormalities of locomotion, "Basic Aspects of Abnormalities of Gait from a Neurologic Standpoint" might have been more appropriate as a title. The colored photography is of excellent quality, and the narration is very well done. The subject is so clearly presented in such simple terms that the film can be used profitably for instruction of a wide range of students, including nurses, physical therapists, occupational therapists, undergraduate medical students, and graduate students of medicine. One neurologist who viewed it commented that even well-trained neurologists would enjoy seeing this film.

Tetralogy of Fallot and Its Surgical Treatment: 16 mm., color, sound, showing time 32 minutes. Prepared by John C. Jones, M.D., University of Southern California. Produced in 1955 by Billy Burke Productions, Hollywood, Calif., for and procurable on loan from E. R. Squibb & Sons, 745 Fifth Ave., New York 22.

This film presents cyanosed children in whom a diagnosis of tetralogy of Fallot has been made. The symptoms and physical signs of this condition are presented in detail. Through a series of excellent drawings, the embryologic development of the heart is presented, as well as the blood flow through the heart, both in the normal patient and in the presence of tetralogy of Fallot. Two types of shunting operations (Blalock-Taussig and Potts-Smith) are illustrated by excellent drawings and by photography during surgery. The children are then shown as active convalescents, much improved in general condition. The general organization, narration, and presentation of this film are outstanding. The photography is very well done. This excellent teaching film is highly recommended to residents in thoracic surgery and any physicians concerned with the diagnosis and treatment of heart disease.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Precautions in the Use of Cortisone for Treatment of Rheumatic Diseases. L. E. Ward. Minnesota Med. 38:304-308 and 322 (May) 1955 [St. Paul].

The use of cortisone and related hormones, such as hydrocortisone, 1-dehydrocortisone (metacortandracin) and corticotropin (ACTH) in the treatment of rheumatic diseases must be attended by certain precautions that can be divided into three categories: (1) selection of the proper disease for treatment, (2) selection of the proper patient having one of these diseases, and (3) selection of proper dosage and attention to other details of management in the course of treatment. Cortisone or related hormones are indicated in rheumatoid arthritis and its variants, acute rheumatic fever, systemic lupus erythematosus, and periarteritis nodosa. Cortisone occasionally may be helpful, but its systemic administration is usually not indicated, in arthritis of hypersensitivity states, acute gouty arthritis, acute nonspecific bursitis, tendinitis, and the shoulder-hand syndrome. In this group of diseases other and simpler measures ordinarily suffice. Cortisone or related hormones should not be given for specific infectious (septic) arthritis, osteoarthritis, primary fibrositis, and psychogenic rheumatism. Absolute contraindications to prolonged use of the hormones are psychoses, adrenal cortical hyperfunction (Cushing's syndrome), tuberculosis, and acute poliomyelitis. Relative contraindications include renal and cardiovascular insufficiency, peptic ulcer, psychoneuroses, osteoporosis, diabetes mellitus, convulsive disorders, and certain severe intercurrent infections. The objective in the treatment of rheumatoid arthritis with cortisone or related hormones should be to achieve as much antirheumatic effect as possible without producing hypercortisonism. Experience suggests that daily doses for prolonged treatment should not exceed the following limits: for men, 50 to 60 mg.; for postmenopausal women, 30 to 35 mg.; and for other women, 40 mg. For acute, self-limited, but potentially damaging diseases, such as rheumatic fever, relatively large doses are used to produce quick suppression of the inflammatory reaction; then a gradually lowered but completely suppressive dose is maintained for the relatively brief course of the disease. Dosage and duration of treatment should be adjusted to the needs of the individual patient. For subacute and chronic diseases presenting occasional acute potentially fatal exacerbations, such as systemic lupus erythematosus, doses of 300 to 1,000 mg. or more per day may be given during the acute stage. Subsequently the dose is decreased, so that during the chronic stage little or no hormone is given. The pituitary-adrenal cortical mechanism is inhibited by long-term treatment with cortisone or corticotropin and, therefore, it cannot react normally to produce increased quantities of needed adrenal cortical hormones in case of stress. Thus in order to prevent the serious consequences of adrenal cortical insufficiency in severe stress, such as major surgical intervention, serious injury or severe intercurrent infection, sufficient additional hormone must be given. A patient treated with cortisone or related hormones should carry a card similar to that carried by a diabetic to inform those who might care for him in an emergency that special care and additional doses of hormone may be required.

Hypertrophic Muscular Dystrophy Associated with Acquired Thyroid Insufficiency in Adults. R. Picard, J. Horeau, J. Kerneis and others. Semaine hôp. Paris 31:1553-1555 (May 2) 1955 (In French) [Paris, France].

A 57-year-old man with hypertrophic muscular dystrophy and thyroid insufficiency was found to have greatly overdeveloped muscles in the legs, with induration, pain, and mechanical myotonia. His basal metabolism rate was -29%. Electrical testing showed a myotonic reaction and hypoexcitability. The amounts of alkaline phosphatase, creatinine, and cholinesterase in the blood were slightly below normal. With thyroid replacement therapy, muscular pain and hypertrophy diminished and the patient's myxedematous syndrome was improved. Such a double response to thyroid therapy was also encountered in 12 of 15 cases reported in the literature. In two instances this therapy was not administered, and in one it was unsuccessful, but that patient had congenital myopathy with associated myxedema. The authors' patient died from fulminating bronchopneumonia. Autopsy revealed lesions in the thyroid gland, but none in the diencephalon. The fibers taken from striated muscles in the affected regions showed great diversity of size, and there was a slight increase in the nuclei of the sarcolemma. That the hypertrophic myopathy with myotonia stems from the thyroid insufficiency present in such patients, or from some common antecedent of both disorders, seems an unavoidable conclusion in view of the therapeutic results obtained with replacement treatment; however, the exact relationship of the two diseases is unknown.

Smoking and Chewing of Tobacco in Relation to Cancer of the Upper Alimentary Tract. L. D. Sanghvi, K. C. M. Rao and V. R. Khanolkar. Brit. M. J. 1:1111-1114 (May 7) 1955 [London, England].

The 1,125 men and 335 women who attended the cancer clinic of the Tata Memorial Hospital in Bombay, India, between 1952 and 1954, were questioned regarding their chewing and smoking habits in relation to cancer of the upper alimentary tract. Of the 1,460 patients, 400 were referred to the cancer clinic for a check-up but did not show any evidence of neoplastic disease and served as controls. Of the remaining 1,060 patients, 840 had cancer of the upper alimentary tract and 220 had cancer in other organs. Of the 840 patients with cancer of the upper alimentary tract 119 had cancer of the buccal mucosa (group 1), 170 cancer of the anterior portion of the tongue, alveolus, palate, lip, and floor of the mouth (group 2), 102 of the esophagus (group 3), 152 of the hypopharynx (group 4), 203 of the base of the tongue (group 5), and 94 of the oropharynx (group 6). The smoking and chewing habits of both men and women in the control group were similar to those of the 220 patients with cancer in organs other than the upper alimentary tract. Women with cancer of the upper alimentary tract showed a higher incidence of smoking and about two and a half times the incidence of chewing compared with the control group. In men the results were more striking in that several gradients were observed in the incidence of habits among the different types of cancer. The habit of chewing was associated with cancer of the oral cavity (group 1 and 2); the combined habit of smoking and chewing was associated with cancer of the hypopharynx and base of the tongue (group 4 and 5); and only smoking was associated with cancer of the esophagus and oropharynx (group 3 and 6). Of the persons who smoked, 88.7% smoked bidis, the Indian form of cigarette. The percentage of smokers and the average number of bidis smoked showed a similar trend in all groups. These results indicate that tobacco may be one of the environmental factors for a large number of patients with cancer of the upper alimentary tract observed at the Tata Memorial Hospital. The habit of chewing tobacco and the associated types of cancer lead to an assumption of

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

the existence of a substance or substances in tobacco that may initiate or promote the production of cancer at the sites of prolonged contact.

Hexamethonium, Hydralazine, and Rauwolfia Serpentina Therapy in Hypertension. M. Markowitz, J. V. Koik, F. K. Hick and R. L. Grissom. Am. J. M. Sc. **229**:486-495 (May) 1955 [Philadelphia].

In order to evaluate the effect of hexamethonium, hydralazine, and Rauwolfia serpentina in patients with hypertensive vascular disease of varying degrees of severity, a clinic for hypertensives was begun by Markowitz and co-workers three years ago. This communication is concerned with the results of therapy in 66 patients. No patient was selected for study unless his diastolic pressure was consistently above 100 mm. Hg. Patients with a known history of primary renal disease or an initial nonprotein nitrogen above 70 mg. per 100 cc. were excluded. The patients selected for treatment were divided into four groups. The group 1 patients, who had mild hypertensive vascular disease, were treated with Rauwolfia serpentina alone. The patients of group 2 were given hexamethonium alone, or in combination with hydralazine and Rauwolfia serpentina. All but one of the group 2 patients had a fixed hypertension as well as organic changes in the heart, kidneys, and optic fundi. Group 3 patients with "malignant" hypertension were treated with hexamethonium, hydralazine, and Rauwolfia serpentina. The finding of papilledema was considered diagnostic of "malignant" hypertension. Group 4 included 12 patients previously treated by sympathectomy, whose diastolic hypertension persisted even in the standing position. These patients were treated with veratrum, hexamethonium, and Rauwolfia serpentina singly or in combination. The patients in all of the groups were seen in the outpatient clinic at frequent intervals. The blood pressure was recorded at each visit in the reclining, sitting, and standing positions. Of 26 patients with benign hypertensive vascular disease treated with Rauwolfia serpentina alone for an average of 10.5 months, 14 achieved a reduction in diastolic pressure of 15 mm. Hg or more. Nineteen patients with severe hypertensive vascular disease, treated with hexamethonium, hydralazine, and Rauwolfia serpentina for an average of 14 months achieved an average reduction in blood pressure (standing) of 45 mm. Hg systolic and 25 mm. Hg diastolic. Thirteen patients with "malignant" hypertension were treated with hexamethonium, hydralazine, and Rauwolfia serpentina. Of the six patients still living, five are white females who had a near normal nonprotein nitrogen initially. All four Negro males in this group died. Hexa- onium proved difficult to use due to repeated episodes of cope. In 66 patients of all types, there have been 10 deaths. nile therapy is drastic in many of the patients, and reduction of blood pressure worsened the clinical well-being of some patients, certain dramatic improvements were obtained, including the reversal of papilledema.

Hypertensive Ischemic Leg Ulcer. E. J. Orbach. Angiology **6**:153-161 (April) 1955 [Baltimore].

Orbach presents the histories of two patients, both 59-year-old women, who had ischemic leg ulcers, which had some, although not all, of the features of an entity first described by Martorell in 1945. The location of the typical ulcer is the area above the external malleolus, especially at the border of the middle and lower third of the leg. Usually but not always the ulcerations are symmetrical. Sometimes there is a pigmented area, or a scar on one leg and an ulceration on the other. The ulcer either starts as a small purple spot, which breaks down, or follows a slight injury. It lacks induration of the margins, is painful and resistant to treatment, and may persist for weeks, months, or even years. These ulcers occur mostly in women. There is always severe hypertension, and so the term "hypertensive ischemic ulcer" has been applied to the condition. Histologically the lesion is usually characterized by subendothelial hyalinosis of the arterioles, which leads to stenosis of the lumen, but the author believes that the syndrome is a clinical rather than a pathological entity. Treatment should be conservative, at least in the beginning. Sympathectomy might be advisable for the existing hypertension, but not for the ulcer alone. The ganglion-blocking agent hexamethonium, which, in addition to a hypotensive effect, also produces peripheral vasodilatation, theoretically appears to be a specific drug for the therapy of hypertensive ischemic ulcers. Locally, the enzymes Varidase and Tryptar produce a medical débridement of the ulcers. Antibiotic agents help to eliminate infection, if the specific antibiotic can be found by bacteriological sensitivity tests. Wound healing may be promoted by incorporation of hyaluronidase, which reduces tissue tension and increases the spread of tissue fluid. Minor surgical procedures consist in minute radiary incisions of the wound margin or in careful scarification of the skin-wound borders with the tip of the scalpel. The wounds should b covered. Sponge rubber incorporated into a supportive bandage which reaches from the metatarsal region up to the area below the knee, will keep the patient ambulatory. If under this treatment the ulcer should not heal within a reasonable time, excision of the ulcer down to the muscle tissue and skin graftin should be done. As a preventive measure patients with sever hypertension should be cautioned to avoid mechanical an thermal injuries to their legs, in the same manner as are diabeti and arteriosclerotic patients. Application of excessive cold an heat, such as ice bags and heating pads, should be forbidde Superficial wounds and abrasions should be cleansed and protected by bandages.

Response of Patients with Leukemia to 8-Azaguanine. J. Colsk L. E. Meiselas, S. J. Rosen and I. Schulman. Blood 10:48 492 (May) 1955 [New York].

The authors used 8-azaguanine, a compound closely rese bling guanine in chemical structure, in the treatment of fo patients with acute leukemia, one with chronic lymphatic le kemia, and one with lymphosarcoma. The drug had a mark retarding effect on the leukemic process in three of four patien with acute leukemia. In one patient with chronic lymphat leukemia and in one patient with lymphosarcoma, regression lymphadenopathy and hepatosplenomegaly resulted, but change in the hematological status occurred. Undesirable derm tological reactions and development of nausea and vomiti limited the amount of this drug that could be administered the individual patient. Cortisone administered concomitant with 8-azaguanine did not prevent the dermatitis. A study the effect of combinations of 8-azaguanine with other antine plastic drugs or with guanase inhibitors in the treatment human leukemia is warranted.

Results Obtained with Total Extract of Brassica Oleracea L. Treatment of Gastroduodenal Ulcer. C. Grugni. Minerva ch **10**:242-247 (March 31) 1955 (In Italian) [Turin, Italy].

"Cabagin," the dehydrated total juice of Brassica oleracea (a cabbage variety), was used in the treatment of 23 patien 7 of whom had gastric ulcer, 12 duodenal ulcer, and 2 gast duodenitis without ulcers. The patients received two capsu of the drug at each meal without any side-effects, but the da dose was reduced to four capsules for a few patients who h lost their appetite. The therapy was continued for about days, and the patients were kept on the same diet they had be receiving with the exception of alcohol, coffee, and tobacc which were not allowed. The drug greatly benefited the subje tive symptoms—heartburn, pain, and aerophagy—in most the patients, but it produced only slight changes in the gast peristalsis and the acidity of the secretion. The posttreatme roentgenograms of 10 patients showed marked improvement 5, with reduction of the niche in some and disappearance the indirect signs of the ulcer and normalization of the gast motility in others. Surgical intervention was required in t patients who did not respond to this therapy. They were fou to have ulcers of long standing, and the marked alterations the gastric walls explained the failure of the drug. The auth states that Cabagin exerts a protective action on the muco by supplying it with those principles that are capable of resto ing the mucosa's natural resistance to the digestive action the gastric juice. Although his experience with Cabagin has bee limited, he believes that it is valuable in the treatment of ulce Generally, if the ulcer involves only the mucosa, good resul can be obtained in 15 days, but in deeper ulcers they can b seen only after prolonged and repeated courses.

ortisone in the Treatment of Infectious Hepatitis. T. E. Huber nd A. T. Wiley. Ann. Int. Med. 42:1011-1025 (May) 1955 ancaster, Pa.].

The use of cortisone in the treatment of infectious hepatitis as based on its stimulating effect on the appetite. The authors resent the data assembled during a period of 17 months when ver 200 patients with infectious hepatitis were treated in the rmy Hospital in Yokohama, Japan. Excluding possible serum epatitis and other liver diseases, and using as a base line an terus index of 25 units, the patients were divided into two roups, one receiving cortisone and the other one serving as a ontrol group. Of those receiving cortisone alternate patients ere given the drug by the oral and the parenteral route. There eemed to be no advantage of the oral form of cortisone therapy ver the parenteral form, or vice versa. Treatment with corti-one caused a more rapid clearing of jaundice, as measured by he average icterus index and serum bilirubin levels, than ccurred in the controls. It caused a more rapid return of the ppetite, and the patients treated with it consumed more food, nd it caused a greater gain in weight than in the controls. The romsulphalein test in the cortisone-treated patients returned to ormal faster than in the controls. The patients treated with ortisone got well faster than did the controls. The authors be-eve that cortisone is of definite value in the treatment of hepa-tis. They do not, however, recommend the use of so potent a rug in the routine therapy of hepatitis, but believe that it should e of great value in those patients with hepatitis who do not espond to conventional treatment.

ontrol of Diabetes and Other Features of Acromegaly Follow-g Treatment with Estrogens. E. P. McCullagh, J. C. Beck, and . A. Schaffenburg. Diabetes 4:13-23 (Jan.-Feb.) 1955 [New ork].

In six women, ranging in age from 24 to 54 years the signs nd symptoms of acromegaly had been present for 1 to 16 ears prior to this study. They had all initially received stil-estrol in gradually increasing doses until a maintenance dose arying between 10 and 60 mg. daily was reached. The two atients who manifested intolerance to this drug were given thinyl estradiol in doses increasing, from 0.15 to 5.0 mg. aily. All these women were treated as outpatients. The large oses of estrogens resulted in clinical improvement in all six atients. The five patients with abnormal glucose tolerance urves showed reversal to normal or nearly normal values. One owed a persistently decreased tolerance during therapy, which as improved, though not completely corrected, by increasing e dosage of estrogens. All patients showed a sustained fall in rum phosphorus levels during estrogen administration. In one e basal metabolic rate fell gradually to normal. In the five in hom hand volumes were observed a decrease occurred with strogenic therapy, confirming the regression of acromegalic atures. Arterial hypertension appeared to be unaffected by is treatment. The effects observed are believed to be due to hibition of the production of growth hormone and possibly ther closely related substances.

epatic Coma: Physiopathology and Treatment with Glutamic cid. R. Cachera. Semaine hôp. Paris 31:1542-1552 (May 2) 955 (In French) [Paris, France].

Hepatic coma has two principal causes: severe acute hepatitis nd cirrhoses of various types. The common denominator in ases of hepatic coma is neither causation, specific hepatic esions, nor definite alterations in the central nervous system. ertain biochemical anomalies are the subject of current re-earch: the intervention of toxic substances, electrolyte and cid-base disturbances, disorders of glucose metabolism, and hose of nitrogen metabolism, especially of ammonia. Of the uthor's 11 patients with deep coma complicating cirrhosis of he liver, the disease was alcoholic in nine, postnecrotic macro-odular in one, and of unknown cause in one. The comas were f two kinds: deferred posthemorrhagic coma following major emorrhages from the digestive tract in four of the cirrhotic atients, and pure hepatic coma in seven. Treatment of the oma in the former group was successful in all patients, but hree died 10 to 45 days later as the result of progressive complications of the cirrhosis. In the latter group, two patients recovered, but the others did not respond to treatment and died. The author stresses the necessity of using combined therapy in hepatic coma. Cortisone injections should be given along with the glutamate. Antibiotics, correction of electrolyte imbalances (especially hypokaliemia), and copious infusions of dextrose are good adjuvants. Hepatic coma no longer presents a necessarily fatal prognosis.

The Problem of Malignant Disease in the Elderly. S. Cade. Practitioner 174:550-555 (May) 1955 [London, England].

The author discusses the treatment in elderly persons of cancer of the breast, colon and rectum, esophagus, tongue and mouth, and urinary bladder, and of reticulum-cell sarcomas. In general, palliation assumes a more important role than it does in younger patients, since long survival time is less interesting to the geriatric patient than is relief from symptoms. To formulate a policy it is necessary to regard cancer in the aged as acute or chronic. The disease falls into two groups: the urgent, in which treatment is an emergency measure, and the "cold," in which treatment may be performed in stages. The urgent or acute case may be early and localized or advanced and disseminated, but is always such that nonintervention will lead to death within a few days. Examples of such cases are acute intestinal obstruction from cancer of the intestine, abscess in the lung from cancer of the bronchus or esophagus, hematemesis from cancer of the stomach, or uremia from involvement of the ureters. The patient with acute cancer always remains an individual problem and, except in patients with intestinal obstruction, treatment should be symptomatic and the simplest possible. It is the chronic case that requires great judgment in management and a revision of treatment from time to time. Repeated treatments for the rest of the patient's life may be necessary. Palliation comprises the methods of treatment directed to the tumor itself, remedies for alleviation of symptoms, dieting, the care of open lesions, and control of discharge or bleeding.

Common Clinical Errors in the Care of the Elderly. F. D. Zeman. Practitioner 174:556-561 (May) 1955 [London, England].

There are four principal sources of error in the diagnosis and treatment of elderly persons. First, a defeatist attitude on the part of the physician examining or treating an aged person can induce in him a harmful laissez-faire policy. Stereotyped diagnostic thinking tends to narrow the possibilities in old people to arteriosclerotic heart disease, cerebral arteriosclerosis, and chronic arthritis, and the physician may overlook remediable conditions that can be detected only by careful clinical and laboratory studies, or even clinically obvious disorders. Mistaken therapy in elderly persons in commonly practiced. Oversedation, unwarranted delaying of operations, or withholding of medicaments, and failure to apply even the simplest psychotherapy are the commonest errors. Finally, the altered reactions of the aged to disease may yield atypical clinical findings. In order to avoid errors in the management of elderly patients, certain general suggestions can be made. The patient's individual background and personal problems must be understood. Social maladjustments may present themselves in the form of bizarre symptoms. The aged patient's good sense should never be underestimated, and full attention should be given to all his complaints. With age there comes a tendency to accept pain and discomfort as inevitable. Each patient must be examined thoroughly, since minor lesions are often disclosed which are remediable and which may cause more discomfort to the patient than serious disorders. It is the physician's task to see that preventive measures against household accidents are taken for the benefit of older people so that unnecessary suffering may be avoided.

Dangers of Inactivity During Automobile Travel. A. Soffer. Am. J. M. Sc. 229:475-476 (May) 1955 [Philadelphia].

Soffer presents the case of a 72-year old woman, who had enjoyed excellent health. Physical examination previous to a trip to Florida disclosed no abnormalities. This trip was made by bus and required about 68 hours. The bus stopped at mealtimes and for a rest period of 15 to 20 minutes between meals.

The patient slept on the bus for each of the three nights of the trip. Toward the end of the trip the patient noted pronounced edema of both lower extremities from the knee to the ankle. After a few days of rest, the patient returned by bus. Slight swelling of the legs persisted on arrival at home. Three days later, the patient had a grand mal convulsion, and two other severe tonic clonic grand mal convulsions occurred within the next 18 hours and were associated with emesis and followed by transient disorientation. The patient was hospitalized. Upon bed rest the edema of the lower extremities disappeared and the patient was made ambulatory in a few days. Since hospitalization and in the past 15 months the patient has experienced no neurological symptoms and no edema of the lower extremities. Peripheral vascular stasis followed by transient cerebral ischemia was the inciting cause of the grand mal convulsions. What occurred here, in an exaggerated form, is related to the cerebral ischemia (syncopal attacks) that occurs secondary to any permanent or transient state that permits excess pooling of blood in the lower extremities. In the author's case the efficiency of venous return reappeared when the patient was placed in the supine position for the first few critical days and then permitted to become ambulatory. A number of instances of thrombosis of the deep leg veins due to long automobile rides have been reported. Pulmonary embolization has been known to follow the appearance of the venous thrombosis. It is urgently recommended that automobile drivers and passengers make frequent stops to permit maximum motion of the legs. In the older age groups, precautionary measures during prolonged automobile trips should include leg bindings, and if edema appears, the trip must be interrupted to permit rest in the supine position.

Aldosterone—A Review. R. Gaunt, A. A. Renzi and J. J. Chart. J. Clin. Endocrinol. **15**:621-646 (May) 1955 [Springfield, Ill.].

Aldosterone, a specific crystalline component of the "amorphous fraction" of adrenal extract recently isolated under the [illegible] of electrocortin, is probably the main endocrine agent that regulates sodium, potassium, and chloride metabolism. It may also be involved in magnesium metabolism. Although it is the most active mineralocorticoid known, its actions are not limited to effects on electrolyte metabolism. In appropriate dosage, its effects can mimic those of hydrocortisone and it has some unique properties of its own. It is not just a more potent desoxycorticosterone; important qualitative as well as quantitative differences are clearly suggested between desoxycorticosterone and aldosterone. There is no evidence that the administration of aldosterone causes the pathological over-dosage effects of desoxycorticosterone when the two steroids are given in doses that are equipotent from the standpoint of sodium retention. The human diseases in which aldosterone may possibly be incriminated as a causative factor are those in which high rates of aldosterone excretion are associated with sodium retention and edema, such as congestive failure or nephrosis, and in the less well-known states of "primary aldosteronism" and "potassium-losing nephritis." In the diseases characterized by edema, it is easier to visualize excess aldosterone as being involved only in certain acute phases than as a causative agent. An understanding of the physiology of the hormone in health and disease must await elucidation of the mechanisms by which its rate of secretion is regulated. Its secretion continues in the absence of the pituitary (as early theory proposed); corticotropin in man and the dog, but perhaps not in the rat, does not affect its rate of secretion; and directly or indirectly its rate of secretion is affected by electrolyte intake. In addition and less certainly, it is possible that growth hormone stimulates its output, and that other corticoids suppress its secretion. The observation that low-salt diets call forth a compensatory secretion of aldosterone means that the effectiveness of such diets is self-limited. The discovery of a means to inhibit aldosterone secretion would provide a welcome therapeutic tool.

Experimental Study on Action of Vitamin B_{12} in Pernicious Anemia: Comparison Between Behavior of Gastric Mucosa and Bone Marrow. L. Celli. Minerva med. 46:467-472 (Feb. 21) 1955 (In Italian) [Turrin, Italy].

The effects of vitamin B_{12} on the gastric mucosa and the bone marrow of four patients with pernicious anemia who had had no previous therapy were studied. Each patient was given orally 40 mcg. of the vitamin combined with the intrinsic factor for 40 days. A sternal puncture, gastroscopic examination, and morphological examination of the peripheral blood was made of each patient before the therapy was instituted. These were repeated every 10 days during the course of the therapy for three times. The sternal puncture and the gastroscopic examination were always made on the same morning. The preparation exerted its action on the peptic cells and on the blood cells concurrently; the return to normal of the endoscopic findings was paralleled by the return to normal of the findings in the marrow. The maturation process of the peptic cells and that of the blood cells that had reverted to an embryonic-like structure was restored. The gastric mucosa began to reacquire a red color, but because it did so before the improvement in the peripheral blood was great enough to justify it, the author believes that the improvement in the color of the mucosa was due not only to improvement in the peripheral blood but also to vasodilatation of the arterial capillaries.

Pernicious Anemia in Norwegian District: Epidemiological Investigation. P. Kolstad. Nord. med. 53:597-601 (April 14) 1955 (In Norwegian) [Stockholm, Sweden].

From 1935 to 1953, 297 patients (127 men and 170 women were discharged from Drammen Hospital with a diagnosis o pernicious anemia; 76% of the patients were between 50 an 80, the youngest was 24, the oldest, 83. On the average 14 ne cases of the disease, or 9.3 per 100,000 inhabitants, are detecte annually in the Buskerud district. Of the 257 patients followe up, 50 died during the period of observation, at an average ag of 71. The most important cause of death was cancer of th stomach. Twenty, or 40% died from this cause, as against a expected 13%. Otherwise the prognosis seems to be good. Mo of the patients who died died with, not from, their pernicio anemia. Half of the patients were living more than 7 years aft establishment of the diagnosis, and 30% more than 10 yea afterward. The disease is apparently endogenous. Familial occu rence was found in 12% of the patients.

Allergy and Diencephalon. A. Jacquelin, M. Roman, R. Slan and others. Semaine hôp. Paris **31**:1480-1486 (April 30) 19 (In French) [Paris, France].

Emotional disturbances of various kinds may result in t establishment of allergic sensitivity to a wide variety of prev ously innocuous substances. The histories of patients with po emotional allergy show that most, if not all, have a congenit vulnerability (often hereditary or familial) to the sensitizi effect of emotion, because they are anxious, hyperemotion hyperexcitable, and generally nervous. The allergic manifest tions shown by these patients may be respiratory (asthm rhinitis, and spasmodic tracheitis), digestive (spasmodic colit attacks of gastric hyperacidity, and gastroduodenal ulcer), cutaneous (urticaria, Quincke's edema, and eczema). House du foods of all kinds, emanations from domestic animals, polle cosmetics, DDT, and the most harmless medicaments, ev aspirin, are among the allergens to which postemotional sens tivity may develop; in fact, the sensitizing substances are usual those encountered in normal living. These facts seem to sho that some disturbance of diencephalic regulation is the essenti mechanism in the production of certain allergic states. Furth support for this theory may be found in the excellent resul obtained by irradiating the hypothalamic-hypophysial regio with small doses of x-rays in patients resistant to other form of antiallergic therapy. The fact that x-ray therapy is genuinel antiallergic, rather than antiasthmatic, antiurticarial, or ant eczematous, was clearly shown in the case of a patient in whom though asthma recurred during the premenopause, it was no precipitated by any of the substances that had been responsibl for her earlier attacks. Recognition of a deficiency in the centra autonomic nervous system and the complex physiochemical enzymatic, and hormonal adjustments under its control, togethe with the resulting reflex vasomotor, edematous, inflammatory and spasmodic disturbances, as the primary cause of allergy pro vides a better explanation for this condition than do the hepati or purely endocrine theories. Treatment, too, will be influence by the new orientation. Remedies now in use should be examined to see whether their effectiveness is not due in some instances to a previously unsuspected effect on the diencephalon, and new forms of therapy should be aimed at restoring the balance in the nervous centers, with preference given to the medicaments least likely to produce unfavorable side-effects or a later aggravation of the disorder.

Allergens in Vegetable Oils. A. F. Essellier, P. Jeanneret, H. R. Marti and H. Rosenmund. J. Allergy **26**:107-112 (March) 1955 [St. Louis].

Parenteral administration of vegetable oils may provoke sensitization, but the allergens contained in these oils are not specific for each kind of oil, since intracutaneous tests with different oils have been shown to yield cross reactions. The skin tests are followed by the same kind of local reactions when the oils are entirely refined, that is, completely freed of proteins, carbohydrates, and free fatty acids. Therefore, such impurities are not the causes of sensitization by natural vegetable oils, and the allergen is either a constituent of the oil itself, or a lipid with similar properties, which was not separated from the glycerides during the refining procedure. To test the hypothesis that triglycerides may be the allergens contained in vegetable oils, the allergenic properties of chemically pure synthetic glycerol-fatty acid esters were tested. Sensitization experiments were performed with chemically pure butyric acid, tributyrin, tripalmitin, and triolein. Serial intracutaneous injections of chemically pure, synthetic glyceryl trioleate (triolein) lead to the same allergic reactions as do vegetable oils, and, therefore, the sensitization by natural vegetable oils can be attributed to fatty acid triglycerides. This sensitization is not accompanied by eosinophilia.

Use of Cortisone or ACTH During Rapid Desensitization of Allergic Patients. E. L. Keeney, H. A. Weiss and C. F. Mohr. J. Allergy **26**:141-149 (March) 1955 [St. Louis].

A patient with diabetes insipidus had developed clinical manifestations of anaphylactic hypersensitivity following treatment with posterior pituitary substances. With the aid of cortisone, the allergic symptoms were controlled and held in abeyance during a period of rapid desensitization with vasopressin tannate in oil. It was possible within a relatively short time to discontinue cortisone therapy and proceed with the required amounts of vasopressin without further allergic reactions to the substance. Encouraged by these results and the implication that cortisone had not interfered with the mechanisms of desensitization, 66 patients, including 8 with the acquired and 58 with the hereditary type of hypersensitivity, were rapidly desensitized with the aid of corticotropin and cortisone. The patients with the acquired type of hypersensitivity included, in addition to the one mentioned with sensitivity to posterior pituitary substances, one with hypersensitivity to insulin, two with hypersensitivity to tetanus antitoxin, and four with hypersensitivity to tetanus toxoid. With the exception of one patient who was sensitive to tetanus toxoid and who received corticotropin during desensitization therapy, the other seven patients were given cortisone orally during desensitization. The two patients sensitive to tetanus antitoxin were given 200 mg. of cortisone within the 12 hours prior to desensitization and 400 mg. of cortisone during the course of desensitization therapy. Desensitization was carried out by starting with the lowest dilution to which they did not give a positive intradermal reaction (that is, if they reacted to 0.1 cc. of a 1:1,000 dilution of tetanus antitoxin, then desensitization was started with 0.1 cc. of a 1:10,000 dilution). Desensitizing doses were given in gradually increasing amounts at intervals of 20 minutes. Treatment was completed in about 14 hours, during which time one patient received 13,550 units and the other 50,000 units of tetanus antitoxin. Of the four patients who gave reactions to tetanus toxoid, three received only two doses of cortisone during desensitization, whereas the fourth received 15 mg. of corticotropin at the time of the first desensitizing dose, 15 mg. halfway through treatment, and 15 mg. at the completion of treatment. The patients with the hereditary type of hypersensitivity had asthma, rhinitis, or eczema either alone or in various combinations. They were desensitized with extracts of pollens, environmental allergens, and vaccines (stock, autogenous, or a mixture). Environmental allergens include extracts made from dust, feathers, animal danders, etc. The pollen extracts were standardized so that 1 cc. of concentrated solution contained 25,000 to 30,000 protein nitrogen units. Environmental extracts contained from 5,000 to 10,000 protein nitrogen units per cubic centimeter of concentrated solution. The concentrated vaccines contained 8 to 10 billion organisms per cubic centimeter. Depending on the degree of skin sensitivity to intradermal tests, desensitization was started with dilutions ranging from 1:1,000,000 to 1:10,000. Concomitant with desensitization therapy, 48 patients were given corticotropin intramuscularly alone; 2 received both corticotropin and cortisone, but not simultaneously; and 8 patients were given only cortisone. The total duration of treatment with corticotropin was 10 to 71 days and with cortisone 12 to 55 days. Cortisone and corticotropin administered simultaneously with specific desensitization did not alter the mechanism of desensitization. While the technique of combining rapid desensitization with the administration of corticotropin or cortisone has been successful, it is not suggested that it be given to all patients with active symptoms of hypersensitivity, but merely when the proper indications arise.

Autoimmunologic Disease. P. A. Cavelti. J. Allergy **26**:95-106 (March) 1955 [St. Louis].

The concept of autoimmunologic disease comprises conditions that are due to the pathogenic effects of antibodies produced by a patient against components of his own tissues. The existence of such conditions in man has been established particularly in the field of hematology. There is experimental evidence that other diseases also may be of this type. Serums prepared against practically every organ and tissue of the body have been studied. On injection in homologous recipients, such serums caused leukopenia, thrombocytopenia, and hemorrhagic purpura-like lesions. Likewise, hepatic lesions have been produced with antiliver serum. So-called nephrotoxic nephritis (Masugi nephritis) is easily obtained by injection of an antikidney serum prepared by immunization of animals of one species with kidney substance of another species. A single injection of nephrotoxic serum can produce a chronic, progressive renal disease extending over months or even years. This suggests that the noxious agent must persist or arise anew in the recipient's body. Autoantibody formation arising from modification of kidney substance damaged by the nephrotoxin, in such a way that it becomes an antigen, could conceivably be the cause. While ordinarily tissue constituents are not antigenic in the same animal or within the same species, modification of such constituents and especially combination with foreign proteins can render them antigenic. High titers of antibodies to rabbit kidney were obtained, and acute glomerulonephritis developed in rabbits injected with rabbit kidney mixed with killed streptococci. In analogy with the experiments with kidney tissue, rats were immunized with mixtures of killed streptococci and rat heart or connective tissue and antibodies were obtained reacting in vitro with extracts of rat heart and connective tissue. Histologically endocardial and myocardial lesions of the rheumatic type were found. Discussing human autoimmunologic disease Cavelti points out that many cases of hemolytic anemia are due to autoantibodies against the patient's red blood cells, that autoantibodies against leukocytes cause granulocytopenia, and that idiopathic thrombocytopenic purpura results from platelet autoantibodies. Autoantibodies reacting in vitro with extracts of human kidney have been found in the serum of patients with glomerulonephritis. The encephalitis following rabies vaccination with virus grown in rabbit brain appears to be a direct parallel to experimental allergic encephalomyelitis, and antibrain antibodies have been demonstrated in the patient's blood. It seems possible that autoimmunologic disease-producing mechanisms constitute a general immune-pathologic principle. Autoimmunologic disease presents a difficult therapeutic problem. Where infection is the inciting cause, its eradication in an early stage is effective, as in prevention of recurrences of rheumatic fever. Blocking or inhibition of antibody production or of the antigen-antibody reaction or a protection of the cells from the damaging effects of antigen antibody reactions are other possibilities. Perhaps adrenal cortical therapy acts by some of these mechanisms. The most desirable approach, however, would be to neutralize autoantibodies as they are formed by administration of the appropriate tissue antigen, particularly if the latter could be obtained as a true hapten, not capable of inciting antibody formation.

Tetanus Prophylaxis: The Duration of Protection from Active Immunization. E. S. Stafford. Surg., Gynec. & Obst. 100:552-554 (May) 1955 [Chicago].

Studies carried out on clinical tetanus indicated that the prophylactic use of a single injection of 1,500 units of tetanus antitoxin does not alter the mortality rate from tetanus. On the other hand, active immunization provides almost perfect protection against tetanus. Persons who have been actively immunized retain a measurable level of tetanus antitoxin in their serums for at least 11 years after the most recent booster injection. These individuals respond rapidly to a new booster injection of toxoid. If the present policy of administering the combined diphtheria-tetanus toxoid to children is continued, eventually nearly all Americans will possess active immunity against tetanus. Meanwhile, it is necessary to have a plan for the prophylaxis of tetanus that will meet all situations. The plan outlined by Stafford stresses the following points. 1. Measures to minimize the opportunity for growth of anaerobic bacteria should be the primary concern in the treatment of injuries. 2. A booster injection of 0.5 ml. of fluid tetanus toxoid should be given intramuscularly to persons known to have received the basic immunizing injections, including all veterans of the United States Armed Forces of and since World War II and many children born since 1937. 3. All other patients are to be divided into two categories: those not sensitive and those sensi- ve to horse serum, as demonstrated by suitable means (the junctival test is preferred). Those not sensitive should receive 00 units of tetanus antitoxin intramuscularly, and those who are sensitive to horse serum should not be given tetanus antitoxin in horse serum but should receive an injection of 0.5 ml. of fluid tetanus toxoid as the initial step in immunizing them. These individuals should then be observed carefully for three weeks, so that if tetanus develops the earliest signs may be detected and prompt treatment instituted. A second injection of toxoid is given after one month, followed four to six weeks later by a third injection. These patients are thus safeguarded against future risk from either tetanus or horse serum. Active immunization against tetanus should be provided particularly to those who live in rural areas and to those whose occupation exposes them to injury. The value of tetanus antitoxin in treating clinical tetanus is unquestioned. Recent work suggests that blood serum drawn from immunized donors of high titer constitutes a readily available source of potent antitoxin. Thus, if tetanus should develop in a patient who, being sensitive to horse serum, has not received prophylactic antitoxin, there is at hand a means of combating the disease at once.

Alterations of Water-Salt Balance in Insufficiency of Posthypophysis and Their Importance in Differential Diagnosis Between Diabetes Insipidus and Psychogenic Polydipsia. G. Gobbato and L. Lacroix. Minerva med. 46:437-445 (Feb. 17) 1955 (In Italian) [Turin, Italy].

The water-salt balance was studied in six patients with diabetes insipidus before and after the administration of extract of the posterior lobe of the hypophysis (the antidiuretic hormone). Significant changes were not present in the glomerular filtrate and the blood urea clearance of these patients. Administration of the antidiuretic hormone in doses of 0.1 to 0.13 units per kilogram of body weight by the intramuscular route caused a marked reduction in diuresis without, however, influencing in any way the glomerular filtrate. The density and the osmotic pressure of the urine were increased, but the renal elimination of the chlorides was not greatly influenced. In four patients there was a notable increase in the total concentration, and therefore in the osmotic pressure, of the plasma and a corresponding proportional increase of the chlorides in the blood. The volume of the extracellular fluids was slightly reduced. The posterior lobe of the hypophysis is highly sensitive to changes in the osmotic pressure of the plasma: an increase in its osmotic pressure stimulates, whereas a decrease inhibits, the secretion of the antidiuretic hormone thus causing a state of polyuria or oliguria respectively. By controlling the renal excretion of water, this lobe regulates also the plasma isotonic pressure. This regulating mechanism is no longer present in patients with diabetes insipidus in whom a decreased or absent secretion of the antidiuretic hormone causes a permanent polyuria. This is followed by a state of simple dehydration with an increased osmotic pressure of the circulating fluids. The increased osmotic pressure of the plasma can no longer stimulate the impaired posterior lobe, polyuria remains unchanged, a tremendous thirst torments the patients, and enormous quantities of fluid are ingested. There are some forms of marked polyuria that are secondary to psychogenic polydipsia and that are difficult to differentiate from the polyuria of diabetes insipidus. In psychogenic polydipsia a great intake of fluids causes a state of hydremia with a decrease in the osmotic pressure of the plasma and therefore an inhibition of the excretion of the posterior lobe of the hypophysis, and the onset of polyuria. Thus in diabetes insipidus polydipsia is secondary to polyuria, whereas in psychogenic polydipsia the reverse is true. Another feature for the differential diagnosis between the two conditions lies in the fact that the urinary flow decreases in patients with psychogenic polydipsia during the intravenous injection of the antidiuretic hormone, whereas in patients with diabetes insipidus it decreases after the injection.

Hereditary Diabetes Insipidus: Report of 20 Cases in Seven Generations. E. L. Levinger and R. F. Escamilla. J. Clin. Endocrinol. 15:547-552 (May) 1955 [Springfield, Ill.].

The occurrence of hereditary diabetes insipidus is reported in a 26-year-old woman, whose urinary output was 13½ quarts (12,771 cc.) daily, and who had a positive reaction to beta-hypophamine (Pitressin) when subjected to the Carter-Robbins test. The course of the disease was complicated by rheumatic heart disease with decompensation and, later, by chronic diarrhea of undetermined origin. The latter improved, and the bothersome nocturia ceased after reinstitution of antidiuretic therapy with 15 mg. of posterior pituitary powder given by nasal insufflation two to four times daily. This therapy had been discontinued temporarily to offset the tendency toward fluid retention from congestive failure. The patient is now comfortably maintained with two or three nasal insufflations of the powder daily, in addition to routine administration of digitalis for her cardiac condition. She stated that the "water habit" was a family characteristic that had been manifested by her mother, grandmother, great-grandmother, and great-great-grandmother, as well as by her maternal aunts and three of her four uncles. Her three children were also affected. Investigation by correspondence and interviews elicited a family tree with 20 cases in seven generations. Genetic analysis showed that the transmission in this family was by simple dominance, by a conditionally dominant gene with poor penetrance without evidence of sex-linkage. This agrees with the opinion expressed in most reports of similar series in the world literature.

Sparganosis: Second Case Reported from South America: First Case Observed in Uruguay. J. J. Osimani and R. Peyrallo. Arch. urug. med. 46:139-148 (March-April) 1954 (In Spanish) [Montevideo, Uruguay].

Sparganosis in human beings is frequent in the Far East and rare in the Western Hemisphere. In the Far East it is found mainly in frogs. A frequent cause of infestation of people is the use of frog meat applied to the eyes or wounds for its alleged therapeutic value. Spontaneous infestation of cats, dogs, members of the weasel family, and rodents has been reported from several countries in the Western Hemisphere. Six cases of sparganosis in human beings have been reported from the United States. They include the only case of proliferant sparganosis ever reported in the Western Hemisphere. The proliferant form follows its course with gross multiplication of larva simulating metastases of malignant tumors and with diffuse involvement of the tissues of several structures. This form is extremely rare. The parasitic infestation of nonproliferant forms is acquired by drinking water contaminated with crustacean of the Cyclops genus harboring procercoid larvae, contact of the skin with contaminated water, or eating meat of infested mammals or fowls. The case reported by the authors is the second one published from South America and the first one observed in Uruguay. The patient, an adult woman, was well until she visited a rural zone and consumed water from a well. A few months later an abscess developed on her leg. After surgical opening of the abscess and complete elimination of pus, a mobile larva appeared at the surgical wound. It was removed and put in alcohol. At microscopic examination it appeared to be a larva of the Diphyllobothrium erinacei 48 mm. long, 1 mm. wide, and with a scolex 1.5 mm. long. Ten months after the operation the patient was in good health. No other parasites were found in the feces either before or after the operation. The authors recommend that in similar cases the larva be preserved alive to be used in experimental infestation of cats and dogs so that the adult form of the parasite may be identified.

Contribution to Study of Treatment of Brucellosis with Hieracium Pilosella. E. Greib and P. Duquénois. Presse méd. **63:** 642-644 (April 30) 1955 (In French) [Paris, France].

Fourteen patients with brucellosis were treated with an extract from the plant Hieracium pilosella, with good results. As has recently been discovered, the fresh plant contains, in addition to bitter and diuretic principles, antibacterial substances derived from umbelliferone. The activity of these substances has been demonstrated in vitro. Like umbelliferone, the methyl-umbelliferones and hydroxy-6 umbelliferone have a bacteriostatic action on Brucella abortus, Br. melitensis, and Br. suis. The drug was administered orally to the patients in question. This method was simple, and no intolerance was noted. Response to therapy was prompt. The treatment should be continued for at least a month; no relapses occurred after such treatment. The success of this trial, especially considering that Hieracium pilosella therapy was effective in patients with brucellosis resistant to other antibiotics and in patients with complications not permitting vaccine therapy, warrants further use of the drug.

SURGERY

Controlled Cross Circulation for Direct-Vision Intracardiac Surgery: Correction of Ventricular Septal Defects, Atrioventricularis Communis, and Tetralogy of Fallot. C. W. Lillehei. Postgrad. Med. **17:**388-396 (May) 1955 [Minneapolis].

Of 30 patients with congenital cardiac defects who underwent operations, all involving open cardiotomy, which were performed since March, 1954, with the aid of controlled cross circulation, 21 had interventricular septal defects, 6 tetralogy of Fallot, 2 atrioventricularis communis, and one isolated infundibular pulmonic stenosis. The only special equipment necessary for controlled cross circulation is a pump unit consisting of an electric motor coupled to a speed changer, the latter being connected to the pump itself. This pump accurately controls the reciprocal transfer of blood between patient and donor. During the interval of the patient's total cardiac bypass, the pump circulates equal amounts of oxygenated blood from the donor's femoral artery to the patient's aorta and, at the same time, an exactly equal amount of venous blood from the patient's venae cavae to the donor's saphenous vein. All the patients had their congenital heart defects completely corrected by the surgeon working within the open heart under direct vision with sufficient time to permit the anatomic correction of the defect or defects present, thus restoring their circulation to normal physiologically. The concept that relatively large quantities of blood flow are needed for safe maintenance of the vital organs during total cardiac bypass was shown to be erroneous. Experiments carried out on dogs showed that the animals survived long periods of complete venal cava occlusion provided only that the amount of blood flowing through their azygos vein was allowed to enter their hearts. This azygos flow was measured, and it was found to be only 8 to 14 cc. per kilogram of body weight per minute, or approximately one-tenth of the so-called resting or basal cardiac output necessary for safe maintenance of the vital centers of the body during total cardiac bypass. Total cardiac bypass at very reduced blood flows, at normal body temperature, based on the experimental studies of the azygos flow has been demonstrated to be perfectly safe in man. The vast simplification made feasible by this need for relatively small quantities of blood for perfusion during total cardiac bypass is the physiological basis of this method and the keystone of success in the field of open intracardiac surgery by means of total cardiac bypass. Direct suture of septal defects proved to be the simplest and most effective method of closing these abnormal openings; of the 21 patients with this type of defect 14 survived and 7 died from 6 to 11 hours after the operation. Ventricular fibrillation did not develop in any of these cases whether the results were successful or unsuccessful. In the patients with tetralogy of Fallot the surgical procedure consisted of suture closure of the ventricular defect with resection of infundibular stenosis. Of the six patients operated on, three died. Suture closure of both atrial and ventricular defects with correction of valvular deformity was done in the patients with atrioventricularis communis; one of the two patients died. Resection of infundibular muscle was the procedure carried out in the patient with isolated infundibular pulmonic stenosis. Conduction difficulties were not a serious problem in intracardiac procedures because of close attention to two factors important for the well-being of the cardiac conduction system, namely, normal body temperature and a well-oxygenated myocardium. It is emphasized that once the myocardium is relieved of its pumping burden, as occurs as soon as venous inflow stasis is effected, it may remain well oxygenated on a mere trickle of oxygenated coronary flow.

The Repair of Experimental Interventricular Septal Defects, During Hypothermia, with a Molded Polyvinyl Sponge. F. J. Lewis and M. Taufic. Surg., Gynec. & Obst. **100:**583-590 (May) 1955 [Chicago].

The authors report a successful method of repairing experimental defects of the ventricular septum with a molded, polyvinyl, plastic sponge. The molded sponge can be inserted rapidly and will be held in place by its own elasticity and one fixation suture. It causes little reaction. The ability of the heart to tolerate the material was confirmed by the authors. Each of the adult mongrel dogs used had two experimental operations, both through the right atrium—one to produce the defect and a second to close it. The defect was made in the high septum by inserting a plastic tube through a stab wound, made just behind the septal leaflet of the tricuspid valve. No tissue was removed. At a second operation the plastic tube was removed and the resulting defect was repaired by inserting the molded, plastic sponge and fixing it in place with one stitch. All of the operations were done under hypothermia. Thirteen of the 15 dogs subjected to this experimental operation have survived. Connective tissue grew into the plastic sponge so that there resulted a firm scar covered with endothelium. There was little inflammation in the adjacent septum. Although this experimental operation was successful, it cannot be concluded that congenital defects may be repaired as satisfactorily by the same method. The experimental defect described here is more nearly like high human defects than other that have been used but it is not identical with them. It is located in the same position but its edge, as formed by the plastic tube, is of almost uniform thickness all around, while the edge of the human defect is thin in one portion and thick in another. The experimental defect does not have the impressive variability in size and shape that is characteristic of congenital defects. Sponge devices can be designed to fit openings of different size and configuration, but all this may not be necessary. Human ventricular septal defects have recently been repaired by simply using interrupted silk stitches. In the experience of these authors, a suture approximation has been satisfactory for the repair of atrial septal defects. It may also prove to be the best method for the complicated defects of the ventricular septum.

Resection or Collapse in the Surgery of Pulmonary Tuberculosis? K. M. Shaw. J. Irish M. A. **36:**109-111 (April) 1955 [Dublin, Ireland].

This report concerns 193 consecutive cases subjected to thoracoplasty or resection. There were 26 pneumonectomies, mainly for totally destroyed lung, with a mortality of 7.7%, and 73 lobectomies and segmental resections, with a mortality of 1.4%. Surgical collapse was accomplished entirely by thoracoplasty. It was carried out in 94 cases, and there was no mortality (fatalities occurring within three months of operation). The classical selective 5-8 rib Semb thoracoplasty with extensive extrafascial apicolysis was the routine operation, the only other operation used being a one-stage "roof" thoracoplasty of the Holst type. The tendency has been to limit the extent of the rib resection more than formerly, 43 cases having had not more than 5 ribs resected. This limitation has been due in part to the more localized type of disease encountered following prolonged drug therapy, but also to a desire to preserve functioning lung. Three patients required lobectomy or segmental resection following 5-rib thoracoplasty, and two required pneumonectomy following 8-rib thoracoplasty; but as the follow-up period has been of only three months in some cases, these figures are likely to increase. The indications for lobectomy and segmental resection are in many cases clear-cut; it is generally accepted that lower lobe disease and localized unstable solid lesions are best treated by resection; however, a large group of cases can be treated satisfactorily by either thoracoplasty or resection, as far as immediate control of disease is concerned. Uncomplicated segmental resection results in no appreciable loss of pulmonary function, and removal of a destroyed lobe is accompanied by less functional loss than the most limited thoracoplasty. A further factor is the cosmetic result of operation. An extensive thoracoplasty with scapular embedding is mutilating and requires considerably more psychological adjustment on the part of the patient than does resection. Perhaps the most important factor in the increasing use of resection is the altered situation following prolonged antibiotic and chemotherapeutic treatment. Filled, inspissated, and small thick-walled residual cavities, ronchial cold abscesses, and multicentric caseous pneumonic ci are among the types of lesion seen more frequently than rmerly, and are suitable for resection rather than thoracolasty. Progressive reduction in the mortality for resection has almost eliminated the safety factor as an argument for thoracoplasty. The ultimate solution of the controversy must await the publication of adequate numbers of long-term results, but meanwhile there is sufficiently encouraging evidence to continue with the cautious use of resection in cases technically suitable for the procedure.

Survival in Breast Cancer Cases in Relation to the Structure of the Primary Tumor and Regional Lymph Nodes. M. M. Black, S. R. Opler and F. D. Speer. Surg., Gynec. & Obst. **100:**543-551 (May) 1955 [Chicago].

In 179 patients with breast cancer followed either to death or for a minimum of five years postoperatively, length of survival was studied in relation to the microscopic structure of the primary tumor and the regional lymph nodes. Excellent survival rates were encountered when the tumors were characterized by highly differentiated structure, lymphoid infiltrate in the primary tumor and sinus histiocytic reactions in the regional lymph nodes. In tumors lacking these features a very low rate of five year survivals exists. These relationships were obtained without regard to the age of the patient or the presence or absence of axillary node metastasis. The findings are consistent with the hypothesis that the lethality of breast carcinoma varies as a direct function of the growth potential of the primary tumor as reflected in the nuclear structure, and inversely as a function of tumor retarding factors of the host visualized as sinus histiocytosis of the regional lymph nodes and lymphoid infiltrate in the primary tumor.

Some Aspects of the Respiratory Function and Some Metabolic Findings During Immediate Postoperative Course Following Surgical Collapse Therapy. D. D'Arcangelo and W. Morgagni. Chir. torac. **8:**47-62 (Feb.) 1955 (In Italian) [Rome, Italy].

The authors studied 13 patients with pulmonary tuberculosis in whom thoracoplasty was performed and 2, in whom an extrapleural pneumothorax was instituted, the morning before the operation and every day during the first postoperative week. They found that after the operation the respiration was more rapid and slightly less deep; the pulmonary ventilation was slightly increased; the oxygen consumption and the pulmonary coefficient of oxygen utilization were increased; the elimination of carbon dioxide was decreased; the respiratory quotient was reduced; the azotemia was increased; the alkali reserve was reduced; and there was a heavy urinary output of total nitrogen, of urea and ammonia nitrogen, and of creatinine, while the renal excretion of the chlorides was diminished. These changes in the respiratory function and the metabolic alterations were present during the immediate postoperative course and tended to return to the initial values within six to seven days. The immediate postoperative course of surgical collapse therapy in patients with pulmonary tuberculosis can be divided into three phases. During the first phase (first, second and third days) the above-mentioned changes are marked; during the second (fourth and fifth days) there is a gradual return to the initial values; and during the third (sixth and seventh days) the values become stationary. The authors suggest making a complete preoperative investigation of the most important organic functions (cardiovascular, respiratory, hepatic, and renal) in tuberculous patients before subjecting them to surgery, to detect eventual functional insufficiencies, reach a better diagnosis, choose the best treatment, and thus prevent a difficult and sometimes fatal postoperative course.

Appendicitis in Persons over Sixty Years of Age. H. A. Theis. Zentralbl. Chir. **80:**463-471 (No. 12) 1955 (In German) [Leipzig, Germany].

During the three years 1951 to 1953, inclusive, 202 patients over 60 years of age were referred to a surgical clinic in Hamburg with a diagnosis of appendicitis. In 71 of these patients the diagnosis of appendicitis was erroneous: in 19 cholecystitis was found, in 13 cholelithiasis, in 7 ureteral calculi, in 6 gastritis or enteritis, in 5 pneumonia, in 5 intestinal infarct, and in 4 cystopyelitis; in others, lesions such as duodenal ulcer, ileus, uterine carcinoma, and sciatica were found. This large number of erroneous diagnoses is understandable, when it is considered that the symptoms of appendicitis in elderly persons are not as typical as in younger patients. Appendectomy was performed on 101 of the patients. In 5 of these the appendix was free from pathologic changes, although their symptoms were typical of appendicitis. The appendix showed signs of inflammation in 10.2% of the patients, phlegmonous changes in 43.2%, perforation in 27.3% (5 of these patients had diffuse peritonitis) and in 19.3% the appendix was obliterated or fibrotic. In only a few of these patients had the clinical symptoms suggested these severe pathologic changes. Conservative treatment was used in 30 patients, either because their general condition was poor or the appendicitis was not acute. The leukocyte count was less than 10,000 per cubic millimeter in 57.1% of the patients; in 28.5% it was between 10,000 and 15,000 per cubic millimeter; and in 14.3% between 15,000 and 20,000 per cubic millimeter. None of these patients had a leukocyte count in excess of 20,000 per cubic millimeter.

Surgical and Pathologic Classification for Cancer of the Cervix: An Evaluation of 250 Cases. J. V. Meigs and W. Liu. Surg., Gynec. & Obst. **100:**555-558 (May) 1955 [Chicago].

The surgical and pathological classification of cancer of the cervix proposed by Meigs and Brunschwig is based on the findings at the time of radical surgery and from the pathological specimen. It is intended for more precise evaluation of the surgical treatment. The following classification is suggested: class O—carcinoma in situ, also known as preinvasive carcinoma; class A—carcinoma strictly confined to the cervix; class Ao—after a positive biopsy of infiltrating carcinoma no tumor is found in the cervix in the surgical specimen; class B—carcinoma extending from the cervix to involve the vagina and corpus (vaginal or uterine extension may be by direct spread or metastatic); class C—carcinoma involving paracervical or paravaginal tissue by direct extension or by lymphatic vessels, or in nodes within such tissues; class D—lymph vessel and node involvement beyond paracervical and paravaginal regions; class E—carcinoma penetrating the serosa, musculature, or mucosa of the bladder or the colon or rectum; and class F—carcinoma involving the pelvic wall. This surgical and pathological classification was applied to 460 patients with cancer of the cervix who were treated with radical pelvic surgery by the staffs of several hospitals between February, 1939, and December, 1953. There were 238 cases of radical hysterectomy with pelvic lymphadenectomy and 12 cases of pelvic exenteration performed five or more years ago. These 250 cases of cancer of the cervix were classified according to the surgical and pathological classification, and the five year results are presented. The five year survival rate for the entire series was 72%. The five year result for all patients in class O was 100%; class A, 82%; class Ao, 93%; class B, 82%; class C, 50%; class D, 37%; class E, 10%; and class F, 0%. The five year survival rate of 160 patients who received no preoperative treatment of any type was 74%; and for patients who had preoperative treatment of one type or another, 67%. Class B seemed to be a mark beyond which the five year survival rate decreased sharply. When the cancer extended vertically from the cervix to the vagina, or to the corpus, or in both directions, the prognosis was good (82% five year survival rate). If the carcinoma spread laterally to involve the paracervical and the paravaginal tissues or to the lymph nodes in these regions (class C or class D), the prognosis was quite different (50 and 37% five year survivals). The authors suggest that emphasis should be made clinically on the separation of stage IIa and stage IIb cases in the international classification of cancer of the cervix. The surgical and pathological classification can be used advantageously in surgically treated patients.

Chondromalacia of the Patella. J. S. Thiemeyer. Virginia M. Month. 82:225-228 (May) 1955 [Richmond, Va.].

The occurrence of chondromalacia of the patella, a degeneration of the articular surface of the patella as evidenced by softening, fibrillation with occasional fissuring, and erosion of cartilage, is reported in 21 patients between the ages of 19 and 50 years, 10 (48.5%) of whom had a history of trauma. Four patients had a history of having sustained a fractured patella, and three had a history of a lateral clipping injury, such as sustained in football. Eight patients had no history of any previous trauma. Pain, swelling, and instability were the most common symptoms. Although crepitation, either audible or palpable and usually subpatellar, has been emphasized as the most characteristic sign of the disease, it was observed in only eight patients (38%). Crepitation indicates cartilage degeneration, but the absence of crepitation does not rule it out, for effusion of the knee, which is often present, might separate the contacting surfaces. Pain on pressing or moving the patella by hand in the trough was observed in 11 patients (55%). Ten patients had had previous surgery consisting of menisectomy in 3, of patella shaved in 2, open reduction of fractured patella in one, synovectomy in one, and type unknown in two. All 21 patients were operated on, and in addition to chondromalacia six other types of abnormal condition of the knee, including mirror image on medial femoral condyle, pressure of loose bodies, osteochondritis dissecans, chronic synovitis, associated medial meniscus injury, and nonunion of fractured patella with fibrous scar tissue throughout the joint, were observed. There is no consensus as to the type of surgery to be performed, including partial or complete chondrectomy and patellectomy, but the author considers patellectomy as the treatment of choice when there is a definite history and pathological evidence of previous fractured patella with rough fragments within the joint.

Free Nail Grafting. C. R. McCash. Brit. J. Plast. Surg. 8:19-33 (April) 1955 [Edinburgh, Scotland].

In 10 cases of nail grafting McCash used three different methods of free grafting; the partial nail graft was used in 4. This procedure is similar to that described by Sheehan using the central section of the great toe nail with nail bed and matrix, but with the difference that the graft extends back to the root of the donor nail to include all the germinal matrix available. The composite nail graft, which was used in three patients, is taken from one of the lesser toes and consists of the complete nail, nail bed, matrix, the nail fold on each side and at the root, and a thin shaving of the upper surface of the terminal phalanx. The complete nail graft, which was also used in three patients, is taken from one of the lesser toes and consists of the nail, nail bed, and matrix but without bone or surrounding skin. The results obtained in these 10 patients indicate that the nail with its germinal matrix behaves like any other epidermal structure, being freely transferable on the same patient, and can retain in its new site its peculiar property of forward growth. In every patient the graft took well initially, becoming vascularized within the first two weeks. Of the three methods of grafting, each yielded one really good result, and these were in the patients in whom exfoliation did not occur. Although in all but one patient a new nail grew after exfoliation, some were brittle and fragmented and others horny in character. The ultimate success from a cosmetic standpoint appears to depend on a complete take of both the germinal and sterile matrix, a good digital blood supply, and a smooth surface beneath the graft. A careful contouring of the recipient bed combined with firm fixation is therefore important. A wire mattress suture placed vertically through the phalanx and center of the graft and tied over two buttons ensures intimate contact between the surfaces. The one button rests on the nail and the other on the finger pulp. This method has the advantage that should the tension prove too great between the buttons it can be eased by untwisting the end of the mattress suture. This suture has been used with satisfactory results in recent cases.

Some Observations on Antibiotic Resistance in a Hundred Strains of "Staphylococcus Aureus" in a Plastic Surgery Unit. P. A. Bramley and J. L. Clarke. Brit. J. Plast. Surg. 8:75-81 (April) 1955 [Edinburgh, Scotland].

The use of antibiotics, both locally and generally, is probably more frequent in plastic than in most other forms of surgery, and the problem of resistance is correspondingly greater. Cultures from 100 clinical micrococcic (staphylococcic) infections in the patients of a plastic unit were tested for sensitivity to seven antibiotics by the method described by Bowie and Gould and checked by the serial tube dilution method. Bearing in mind that one cannot claim any great precision in reporting in vitro sensitivity tests and that they must be interpreted in the light of possible serum levels of antibiotic and in relation to the standard Oxford micrococcus, the following results are reported: 68% were fully resistant to penicillin, 64% to streptomycin, 67% to chloramphenicol, 37% to chlortetracycline and oxytetracycline, and no strains resistant to carbomycin and erythromycin were found. Thirty-seven per cent of the strains were insensitive to all the antibiotics, with the exception of erythromycin and carbomycin. Phage-typing showed that the resistant organisms belonged to three well-defined types only. In five patients an apparent change of sensitivity of infecting organism was found to have been due to a cross infection. A small group of micrococcic infections in the general population was tested, and all were fully sensitive to all the antibiotics. These results emphasize the necessity of laboratory control of antibiotic treatment of hospital patients and the care that must be exercised in the selection of antibiotics for prophylactic use. It appears that in the treatment of micrococcic infections in the general population such close control by laboratory methods is unnecessary.

Storage and Use of Arterial Grafts. R. E. Horton. Brit. J. Plast. Surg. 8:9-18 (April) 1955 [Edinburgh, Scotland].

Grafts that were used in the patients here described were prepared by the freeze-drying method and were stored at -79 C. Arterial grafting is now being used in a variety of circumstances in which arterial reconstruction is indicated. Reports from Korea have shown that the prognosis of femoral and popliteal artery injuries has been greatly improved by grafting. Peripheral aneurysms, in the past, were generally treated by ligation to encourage complete clotting within the aneurysm. The use of an arterial graft makes radical treatment possible without detriment to the circulation. In the patient described to illustrate the use of an arterial graft in cases of aneurysm, the artery was transected above and below the aneurysm, an arterial graft was inserted, and the sac of the aneurysm was closed over the graft. The peripheral pulses were felt at the end of the operation, and the limb circulation remained normal. Arterial grafting is also used in treating primary arterial thrombosis. Furthermore, the resection of some neoplasms may require arterial repair. If, in a patient with fibrosarcoma of the thigh, resection involves sacrifice of the femoral vessels, restoration of the arterial flow will insure viability of the limb. In a patient with atheroma, operation on the main arteries of the leg is justifiable only when the disease is severe in the limbs and spares the coronary and cerebral circulations. Operation is considered in intermittent claudication only when the disability is severe enough to cause interference with work, but the proportion of patients suitable for operation is small. Those with rest pain are particularly suitable for grafting, because the alternative is a major amputation. Those with gangrene usually are not suitable for grafting, except when the reduced blood flow is due to an iliac and a femoral block. In such a patient grafting the iliac artery gives a strong pulsatile flow to the profunda femoris artery and this may be sufficient to maintain the foot through the anastomosis round the knee joint. Although there have been disappointments, 16 of 26 arterial grafts were immediately successful, but only time will tell what the late results of grafting will be.

The Surgical Treatment of Human Hypertension. J. E. Thompson, R. D. Bush, G. P. Whitelaw and R. S. Smithwick. *J. Am. Geriatrics Soc.* 3:248-258 (April) 1955 [Baltimore].

Of 1,733 patients with persistent hypertension admitted to the Massachusetts Memorial Hospitals in Boston, 1,226 were operated on and 467 received medical treatment and served as controls. The patients in both groups were followed up for five years or more. The prognosis for a patient with hypertension varies according to the status of his cardiovascular system. Each of the various factors that have a bearing on prognosis, such as age, cerebrovascular accidents, abnormal electrocardiogram, enlarged heart, impending congestive failure, moderate angina, and phenolsulfonphthalein concentration in the urine, was assigned a numerical value, and in every patient the existing factors were totaled, resulting in the numerical grade for the patient. The patients then were classified in four groups; if the numerical grade was less than 4, the patient was placed in group 1 or 2; if the numerical grade was 4 or more, the patient was placed in group 3 or 4. Patients in group 1 had the least severe cardiovascular disease, whereas those in group 4 had the most severe degree of cardiovascular damage. Of the 1,733 patients, 1,525 (88%) had manifest vascular disease either in the eyes, heart, kidney, or brain and were therefore in the stage of hypertension when cardiovascular complications had begun to occur. The average age of the surgical patients was 42 years and that of the medical patients was 45 years. The mortality rate at five years for the surgical patients was 19%, and that for the medical patients was 54%. Thoracolumbar splanchnicectomy was the surgical procedure employed in 93% of the surgically treated patients with essential or malignant hypertension; an additional 7% underwent transthoracic sympathectomy and splanchnicectomy. The operative mortality after splanchnicectomy was 0.7% in patients of group 1, 1.4% in group 2, 4.3% in group 3, and 10.9% in group 4, with an over-all operative mortality of 2.8%. Total and subtotal adrenalectomy and nephrectomy are the other current surgical measures that are available for the treatment of the small group of patients with hypertension caused by pheochromocytoma, adrenocortical adenoma, unilateral renal disease, coarctation of the aorta, and Cushing's disease (adrenal cortical hyperfunction). Splanchnicectomy is the treatment of first choice for male patients and certain female patients with essential or malignant hypertension in group 1, and it is also the treatment of first choice for male and female patients in group 2 and 3. Splanchnicectomy is justifiable in male and female patients of group 4 with severe cardiovascular disease provided renal function is still adequate and cerebral damage is not too extensive. The late results are poor at best in most patients of group 4 despite surgical procedures, either alone or combined with the best medical treatment. It is therefore urged that splanchnicectomy be utilized before the hypertension progresses to the group 4 stage.

Troubles in Gallbladder Surgery. H. G. Bell. West J. Surg. 63: 192-195 (April) 1955 [Portland, Ore.].

During the past 24 years 1,335 cholecystectomies were carried out at the University of California Medical Center. This number included 1,085 simple cholecystectomies and 250 cholecystectomies that were combined with exploration of the common duct. Only one of the patients in whom simple cholecystectomy was done returned within a three-year period with evidence of a common duct stone. Unfortunately, this state institution not have a long-time follow-up on all patients with sin cholecystectomy, so that it is not definitely known whether n should have been subjected to exploration of the common d The mortality rate was 1.01% in simple cholecystectomy, c pared to 2% in the patients who required exploration of common duct. It was not possible to make cholangiogr routinely, and Bell feels that the routine use of this metho not necessary, especially since it adds to the length and hazard of the operation. Of the 250 patients in whom common duct had been explored 13 required reoperation six of these, stones were found, two had cirrhosis of the l and five had strictures or spasm of Oddi's sphincter. Seventy- patients required further surgical treatment after previous o ations at other hospitals. The author makes no attempt to dis all possible complications of biliary tract surgery, but str two points: First, surgery of the gallbladder should be done since there is no real medical treatment, and an incision sh be used that will provide adequate exposure. Second, in m cases common duct exploration is being done unnecess and unwisely. He does not believe that any one can exp dilate, or curet a chronically strictured tube without ca further scarring and narrowing of that tube. Unless there very definite indication for exploration, he prefers to leav common duct alone, particularly if the duct is chroni thickened.

Ulcerative Colitis Treated by Total Colectomy and Ileo-R ***Anastomosis.*** *S. Aylett. Brit. M. J. 1:1060-1062 (April 30)* [London, England].

Ten female and seven male patients with ulcerative c between the ages of 10 and 51 years, in whom the rectum not already been irretrievably damaged by gross fibrosis perirectal suppuration and fistula formation were subject a total colectomy and ileorectal anastomosis. Although i first few cases the ileum was anastomosed to the rectum upper third the establishment of a safety-valve opening i left iliac fossa necessitated the retention of the lowermost p of the pelvic colon. This severely diseased portion of the intestine may be included in the excision if the rectum is lized as an initial stage in the operation by division of the part of its lateral ligaments and its posterior attachments. the ileorectal anastomosis has been carried out the colec is completed by transecting the rectum through its upper about 2 cm. above this anastomosis. It is then possible, result of the mobilization of the rectum, to exteriorize its upper end through the lowermost part of the paramedia sion to act as a safety valve. Such a safety valve may mi the danger of a breakdown of the line of anastomosis, ma it is through a diseased rectal wall. This proctostomy te undergo spontaneous closure more readily than a colosto the left iliac fossa, so that the necessity for its closure by o tion is required less often. Most of the patients were ope on in one stage and in only one of the last 10, a grave patient with an acute case, the colon was excised and ileos established as an initial stage of the treatment, the upper e the rectum being exteriorized and restoration of continuity delayed until the patient had been restored to good health but one of these severely and sometimes desperately ill pa returned to good health and to full work. These results see indicate that the method of treatment described is a satisfa one. The follow-up varying from four months to three yea short, and the author's series is not large. Nevertheless in no has the disease flared up in the remaining rectum, and re proctoscopic examination has shown that resolution of inflammatory changes existing before the operation has t place. Of two additional patients in whom the caecum see at operation to be so little diseased that in each it was reta and the anastomosis was effected between it and the rectum, remained perfectly well for 18 months, while the other h severe and uncontrollable hemorrhage four months after operation. On repeated operation the caecum was found t acutely inflamed; it was resected and an anastomosis was formed between the terminal ileum and rectum. Unless caecum is absolutely normal no attempt should be made retain it.

Emergency Pneumonectomy for Uncontrollable Hemoptyses of Tuberculous Origin. L. Sommo. Minerva chir. **10**:128-134 (Feb. 15) 1955 (In Italian) [Turin, Italy].

A successful emergency pneumonectomy for massive hemoptyses complicating pulmonary tuberculosis in a 25-year-old man is reported. A left extrapleural pneumothorax and a pneumoperitoneum had been instituted to control the hemoptyses but both had failed to do so. Large doses of coagulation-stimulating agents had also been given but with little or no benefit. Because of the patient's poor general condition, a pneumonectomy of the left lung was performed. It revealed a large cavity, which had eroded a subsegmental branch of the artery of the apical segment of the lower lobe. The histological diagnosis was disseminated, nodular, fibrocaseous, and fibrocaseous tuberculosis of the left lung, mainly of the lower lobe; active cavitary lesion with caseous walls in the apical segment of the lower lobe with signs of recent posterobasal hemorrhage; and bronchogenic hemorrhagic flooding of the entire parenchyma of the lower lobe. After 15 days the patient was discharged from the surgical ward at which time roentgenograms revealed no lesions in the contralateral lung. Although pulmonary resection is not the treatment of choice for massive, uncontrollable hemoptyses in patients with pulmonary tuberculosis, it can become (as in this case) a life-saving measure in patients in whom other methods of treatment have failed. This method has not, however, found wide acceptance because of (1) the risk involved in performing the operation when the patient is in shock; (2) the possibility of massive tracheobronchial flooding followed by death owing to internal submersion; and (3) the possibility of bronchogenic spread of the disease. The author's case and other reported cases show that pulmonary resection can be performed successfully in patients in whom massive hemoptyses complicate pulmonary tuberculosis.

The Problem of Nutrition Following Total Gastrectomy. A. H. Johnson, H. J. McCorkle and H. A. Harper. Gastroenterology **28**:360-366 (March) 1955 [Baltimore].

The effect of total gastrectomy on the nutritional status of 36 patients operated on at the University of California hospital was studied. Of the 36 patients, 31 underwent total gastrectomy for carcinoma of the stomach, 3 for benign gastric ulcer, one for a benign gastric polyp, and one for a lymphosarcoma. Total gastrectomy was performed on 116 adult dogs, and the animals were studied with respect to their postoperative nutritional status. The clinical and laboratory observations made on these gastrectomized patients and animals indicate that alimentation time is decreased after complete gastrectomy. The amount of carbohydrate, fat, and protein absorbed is much less than normal. There is a tendency to regain some weight and maintain better nutrition when continuity is maintained between the esophagus and duodenum. This can be accomplished either by direct anastomosis between the esophagus and duodenum or by transplantation of isoperistaltic segments of colon or jejunum between the esophagus and duodenum. Digestion and nutrition appears to be better in patients with isoperistaltic colon segment transplants, and this procedure seems to be worthy of further trial even though it is technically more difficult to perform.

Hypophysectomy in Man: Effect on Water Excretion During the First Two Postoperative Months. D. Ikkos, R. Luft and H. Olivecrona. J. Clin. Endocrinol. **15**:553-567 (May) 1955 [Springfield, Ill.].

The changes in water excretion in the course of the first two months after hypophysectomy and the effect of cortisone on these changes were studied in 22 patients with metastatic cancer of the breast and in 2 patients with metastatic cancer of the prostate at the Serafimerlasarettet in Stockholm, Sweden. Hypophysectomy induced a polyuria interrupted by a short period with lower urine volumes (normal interphase) that occurred about the end of the first week. The persistence of this polyuria after the third postoperative week depended on cortisone administration. The mean specific gravity of the daily urine was below 1.010 during the administration of cortisone and was increased when cortisone was discontinued. The response to a water-load test was abnormal when cortisone was not given. A 24-hour thirst test did not induce an increase in the specific gravity of the urine, whether cortisone was given or not. The observations are interpreted as showing that the presence of the posterior lobe of the pituitary is not a prerequisite for the "normal interphase" in man; that one of the mediators of the diuretic action of the anterior lobe of the pituitary is corticotropin; and that antidiuretic hormone is probably present in hypophysectomized patients but is produced and/or released in an abnormal fashion.

Cancer of the Esophagus. C. B. Puestow, W. J. Gillesby and V. L. Guynn. A. M. A. Arch. Surg. **70**:662-671 (May) 1955 [Chicago].

In the past few years the incidence of carcinoma of the esophagus has represented about 0.1% of the total hospital admissions. Carcinoma of the esophagus represents about 3% of admissions for primary malignant disease. About 90% of carcinomas of the esophagus are squamous cell carcinomas, and about 10% are adenocarcinomas. Since most esophageal adenocarcinomas are found near the esophagogastric junction, many adenocarcinomas found at the lower end of the esophagus may be primary in the stomach extending into the esophagus. Five adenocarcinomas in the authors' series of 603 were definitely above the level of the cardia. The prognosis in adenocarcinoma of the esophagus is better than that of squamous cell carcinoma. Pulmonary complications are present in a high percentage of patients with esophageal obstruction owing to aspiration of saliva into the tracheobronchial tree. X-ray therapy has limited value and presents definite hazards. The authors prefer surgical intervention. The operative mortality is decreasing, and the survival after operation shows that it is worth the effort. The authors ligate the esophagus above and below the tumor in the early stages of resection, in order to prevent exfoliation and inclusion of carcinoma cells in the line of suture. Lymphatic extension of the disease is probably more extensive than has been realized, and surgical excision will have to be extended if better results are to be expected. The authors prefer the left-sided approach.

Hypotension and Hypothermia in Surgery of Thoracic Aorta. O. C. Julian, W. J. Grove, W. S. Dye and others. A. M. A. Arch. Surg. **70**:729-738 (May) 1955 [Chicago].

The authors combined the techniques of hypotension and hypothermia in nine patients undergoing coarctation resection requiring graft replacement and in two patients undergoing resection of the upper thoracic aorta for aneurysm. The aneurysms were situated immediately beneath the left subclavian branch of the aorta in each case, and, in one, arteriosclerotic changes in the left subclavian artery had resulted in its complete occlusion. No evidence of ischemic damage to organs developed in any of the 11 patients. None of the nine patients operated on for coarctation died, but one of the two patients having resection of a thoracic aneurysm died on the 12th postoperative day. Although the period of occlusion was 68 minutes, there was no evidence of spinal cord or visceral damage. This man had an uneventful course until the 12th day. He died from hemorrhage resulting from a coughing spell. In the nine patients in whom hypothermia was used in preparation for resection of coarctation, the defect was closed with a preserved homologous graft. No untoward effects were noted from the combined use of hypotension and hypothermia.

Arterial Embolectomy. W. S. Dye, J. Olwin, H. Javid and O. C. Julian. A. M. A. Arch. Surg. **70**:715-722 (May) 1955 [Chicago].

During the years 1947 to 1953 the authors performed 65 embolectomies on 57 patients. Thirty-eight embolectomies in 33 patients were successful, that is, pulses were restored. Twenty-seven embolectomies in 24 patients failed. Included in these 27 failures are 6 that were technically successful in so far as the removal of the embolus and immediate restoration of pulses were concerned but in which the patient died at periods of five days to five months after the operation. There were 20 deaths in all, 14 occurring in the immediate postoperative period and six within six months after operation. The failures were related more to the precarious cardiac status of the patient at the time of operation than to any other factor. The time interval from the onset of the embolus is important, as 34 of the successful cases were operated on within the first 12 hours. Emboli were removed from the aortic bifurcation in six patients but only three lived; the other three died postoperatively in heart failure. In the three successful cases the patients were operated on within 12 hours of the onset and the operation resulted in restoration of pulses distally. This series of cases represents a positive surgical approach to arterial embolism. Embolectomies were attempted in many patients whose general condition was poor. Proponents of conservative treatment emphasize the high mortality associated with operation, and point out that spontaneous recovery is observed in some patients with acute embolic obstruction. The authors favor surgical treatment, not only because most emboli may be removed under local anesthesia, and the additional shock of the operation is minimal, but also because it is often difficult to distinguish between embolism and thrombosis. In most patients seen as emergencies one does not have records of previous pulses, and age and mode of onset of symptoms may be misleading. As a result, the authors believe all patients should be explored if there is any doubt as to differentiation between thrombosis and embolus. An acute arterial obstruction unrelieved by the release of arterial spasm should be surgically explored, particularly when it can be done under local anesthesia with little risk to the patient. Embolism of the aortic bifurcation constitutes a separate problem because of the need of general or spinal anesthesia. Although this is particularly true in the critically ill cardiac patient, exploration should be undertaken if at all possible since preservation of limb or life is rare without it.

Simple Mastectomy for Carcinoma of the Breast—Reported Results. W. R. Deaton Jr. Surgery **37**:720-725 (May) 1955 [St. Louis].

Radical mastectomy is physiologically, psychologically, and cosmetically mutilating. Although it has a low mortality, it may leave the patient with a useless arm, and postoperative chest pain is not uncommon. Simple mastectomy and irradiation therapy would be a more desirable method of treating carcinoma of the breast if the results at least equaled those obtained with radical mastectomy. McWhirter of Edinburgh, Scotland, recently reported that simple mastectomy and roentgenotherapy had produced better results, in his hands, than had radical mastectomy. Deaton believes that if McWhirter's observation could be substantiated, the prevailing opinions on the treatment of breast cancer would have to be modified. In an effort to evaluate McWhirter's results, reports by other investigators on the treatment of breast carcinoma by simple mastectomy and irradiation were tabulated; the average five-year survival rate for 808 patients was 59.6%. The average five-year survival rate following radical mastectomy, as reported by several authors, for 2,955 patients was 54.5%. The difference (5.1%) in the two survival rates amounts to over twice the value of the standard error of the difference (2.2). Case selection may weight these statistics, but all patients treated by radical mastectomy were theoretically curable and many treated by simple mastectomy were not. Other factors, such as pathological type of cancer, grade of malignancy, duration of disease at time of treatment, and age of patient at time of treatment, may influence the results, but the reports cited do not give sufficient detail to permit adequate detailed comparative studies. McWhirter's explanation for the apparent success of simple mastectomy and irradiation is based on three factors. 1. If the disease is confined to the breast, simple mastectomy will provide a cure. 2. If the regional nodes are involved, surgery often fails to produce a cure. Since irradiation is acknowledged to be beneficial in recurrences and metastases, its use should likewise inactivate the tumor cells. 3. If the malignant cells have spread beyond the regional nodes, no method of therapy succeeds. Many believe that the nature of the cancer and not the type of treatment determines the outcome.

Experience with Extrapleural Pneumothorax: Late Follow-Up Results in 179 Patients. A. Pulin and G. Ballarin. Chir. torac. 8:63-78 (Feb.) 1955 (In Italian) [Rome, Italy].

A follow-up was made of 182 patients with pulmonary tuberculosis who were treated by extrapleural pneumothorax between 1947 and 1951. Two patients could not be traced and in one the follow-up was inadequate. Eighteen patients were dead, 12 of these having died within the first two postoperative years (early death). Death was due to infection of the pleural cavity in 3, cardiac and respiratory insufficiency in 3 in whom the pneumothorax was ineffective and the disease had remained active, and homolateral or contralateral development of lesions in 10 in whom the lung reexpanded before the lesion had healed. The results were unsatisfactory in 26 patients, in 7 of whom a contralateral lesion was present, and satisfactory in 135, in 72 of whom the lung had reexpanded completely. The greatest number of patients with reexpansion of the lung in whom the results were good was found among those in whom the lung had remained collapsed for two and a half to five years. The lung should remain collapsed at least 18 months to insure good results. In fact, although the results were good in 14 patients in whom the lung had reexpanded in a shorter time, they were unsatisfactory in 6, and 15 others had died. The outcome of an extrapleural pneumothorax depends on the topography and the nature of the lesion, the chance of recovery being greater when the coexisting parenchymal alterations are not marked and the cavity is located in the upper zones. Complications—hemorrhage and clot formation, infection of the pleural cavity, empyema, and others—are common, and they greatly influence the final outcome of the treatment. Complications had occurred in 90 of the authors' patients. The follow-up revealed satisfactory results in 57 of these and unsatisfactory results in 18 together with 12 early deaths and 3 late deaths. Of the 89 patients in whom complications did not occur, the results were satisfactory in 78 and unsatisfactory in 8 (there were three late deaths among these). The findings in these patients are not unlike those observed after thoracoplasty or pulmonary resection. The authors [illegible] good results in 75.4% of the patients, but they believe that with a more suitable selection of the patients for extrapleural pneumothorax good results could be obtained in 92%. Patients for whom this operation is especially indicated are those who have a lesion that is relatively small, recent, located in the upper zones, and with pericavitary tissue that is relatively healthy or infiltrated but without signs of parenchymal fibrosis, sclerosis, or atelectasis, and who have a low sedimentation rate without a history of exudative pleurisy or intrapleural pneumothorax.

Segmental Colitis: Results of Surgery. J. H. Manning, R. Warren and A. S. Adi. New England J. Med. **252**:850-853 (May 19) 1955 [Boston].

Segmental colitis, also referred to as regional colitis and [illegible] sided colitis, has been defined as a chronic, nonspecific or cryp genic inflammatory ulcerative or hyperplastic lesion, involvi long, short, or multiple segments of the colon. To further clar the distinction between segmental colitis and the more comm and discrete clinical entities of ulcerative colitis and regio enteritis, the authors require for the diagnosis of segmental c tis, an inflammatory disease involving primarily the colon b sparing, initially at least, the rectum. Thirty-four patients (males and 19 females) seen by the authors between 1935 a 1952 satisfied this criterion. Patients with secondary involveme of the ileum of a lesser extent than that of the colon were not e cluded, nor were those whose disease later spread to the rectu Involvement of the ileum was present in 25 patients. Each the 34 patients in this series was subjected to an anastomot operation with or without resection of the involved intestin The operation rendered 19 of the patients asymptomatic for a average period of 4.6 years, but roentgenologic or proctoscop examination revealed evidence of mild persistent or recurre disease in five of these asymptomatic patients. The 19 asymp matic patients included 15 of the 24 who had undergone rese tion and 4 of the 10 in whom the involved intestine had no been resected. The anastomotic operations failed in 15 patie 7 of whom were restored to health by ileostomy, so that 2 patients obtained a symptomatic cure. Of the remaining eig patients, five died and three were not relieved of their symptom Carcinoma of the colon developed in two of the patients. Seg mental colitis occupies a midposition clinically and pathologica between ulcerative colitis and regional ileitis. Surgical manag ment is necessary in most patients. An ileosigmoidostomy do not cause disability from diarrhea unless there is recurrence o the disease. Because it is not possible to predict in which patien sease will recur after an anastomotic operation, such an ion should be attempted in most patients before an ileos- is performed. Unless there is a definite contraindication on of the diseased intestine should be performed simul- isly with the anastomosis or at a later date.

of Cushing's Syndrome of Unknown Pathogenesis Treated ally by Unilateral Adrenalectomy: Results After Two G. M. Molinatti, A. Pizzini and R. Nejrotti. Minerva 46:650-656 (March 10) 1955 (In Italian) [Turin, Italy].

ase of adrenal cortical hyperfunction (Cushing's syndrome) rapid onset and development is reported in a 33-year-old r. When first seen he had clinical signs typical of the con- , and the laboratory tests revealed an extremely high uri- output of the 17-ketosteroids (116.4 mg.), while that of the oids was only slightly increased. Because the roentgeno- failed to reveal the presence of a suprarenal mass, it was lt to establish the origin of the condition. An exploratory tion confirmed the findings of the roentgenograms. Al- h both adrenals appeared normal in shape and volume, f them was removed. Histological studies revealed no struc- and cellular alterations, but there was a marked increase lipids in the three layers of the adrenal cortex. Immedi- after the adrenalectomy, the daily urinary excretion of -ketosteroids decreased rapidly and progressively (66 mg. ays later) whereas that of the corticoids increased. The t was followed for two years, during which time the excre- f the 17-ketosteroids remained slightly higher than normal, hat of the corticoids, aside from the brief postoperative se, did not change substantially, although it did show a tendency to increase. As for the clinical signs, the diabetes e obesity that were present when the patient was first seen t change; the cutaneous alterations and the hypertension moderately improved; the muscular strength and hemato- l findings returned to normal; and the impotence disap- d. Despite this improvement, however, a certain degree peractivity of the adrenal cortex was still evident at the of writing. The absence of neoplasms in both adrenals, the gs in the adrenal that was removed, and the difference en the preoperative and postoperative course of the con- suggest that the Cushing's syndrome was caused by a ry cortical adrenal hyperfunction without hyperplasia. This ndicates that it is impossible to diagnose a malignant neo- of the adrenal cortex on the basis of hormonal studies

lness of Mean Erythrocyte Volume in Surgical Interven- n the Thorax. W. Köle and K. Paul. Wien. med. Wchnschr. 1-393 (May 14) 1955 (In German) [Vienna, Austria].

20 healthy men and 20 healthy women the mean erythro- olume according to Moro's method was determined as e index by the relation of total erythrocyte volume to the er of erythrocytes per cubic centimeter of blood. The mean in men were 99μ, and in women 101μ, i. e., an index of e mean erythrocyte volume also was determined in patients pulmonary tuberculosis before they underwent surgical nent and after surgical treatment consisting of extrapleural nonolysis, apicolysis combined with thoracoplasty, lobec- and pneumonectomy. The mean erythrocyte volume of its with extrapleural pneumothorax was similar to that of y persons. In these patients the reduction of respiratory e was compensated for by polyglobulism with normal erythrocyte volume or by the healthy circulatory system, reduction of the respiratory surface was so slight that anisms of compensation were not manifest. The mean ocyte volume of patients with lobectomy was moderately gnificantly increased, and this increase was even more pro- ed in patients with pneumonectomy. An increase of mean ocyte volume before the surgical intervention suggests that demands have already been made by the circulation and ythropoietic system on the patient's capacity for compensa- values of mean erythrocyte volume exceeding 1.2 must be dered as definite contraindication for surgical intervention. minations of total erythrocyte volume and of mean erythrocyte volume are indispensable in the course of the clinical examination of patients with pulmonary tuberculosis before a decision concerning surgical intervention on the thorax is made.

Fractures of the Upper Extremity in Children. J. C. Ivins. Minnesota Med. 38:296-298 (May) 1955 [St. Paul].

A plea is made for conservatism in treating fractures in children. The heavy periosteum that surrounds the bone in children may help to prevent displacement. Most of the time it makes for satisfactory manipulation and easier closed reduction. Nature will do a wonderful job in healing these fractures and normal function will be restored, as a rule, if physicians will simply assist nature to the extent of restoring alignment and providing proper immobilization for an adequate length of time. Thus completely satisfactory results can be obtained by traction or by closed manipulation and immobilization in plaster. Certain epiphysial injuries at the elbow may require open reduction when the aponeurosis is completely torn and the condylar fragment is rotated completely out of the joint and turned upside down or when avulsion of the internal epicondyle is associated with complete outward displacement of the elbow and frequently with damage to the ulnar nerve. The head of the radius in children must never be excised; in case of marked displacement of the upper radial epiphysis a short incision may be necessary to restore the parts under direct vision, and a Kirschner wire can be introduced from the back of the elbow through the capitellum into the shaft of the radius to hold its position for two or three weeks until early formation of callus occurs.

NEUROLOGY & PSYCHIATRY

Risk of Paralytic and Nonparalytic Forms of Poliomyelitis to Household Contacts in Nonepidemic Years. M. Siegel, M. Greenberg and P. Stone Jr. New England J. Med. 252:752-756 (May 5) 1955 [Boston].

The primary objective of this study was to determine the probability of clinical infection among household members after the occurrence of poliomyelitis in a member. Data bearing on these problems have been collected in New York City since 1949. The results obtained in the 1949 epidemic were reported previously. The data obtained in the succeeding nonepidemic years, from 1950 to 1953, inclusive, are described in the present communication. Data were obtained from 3,028 household units in which one or more cases of poliomyelitis occurred during the four-year period of observation. Multiple cases were reported in 2.7% of these households. It was found that the probability that paralytic infection would develop in household members after the onset of a case in the family was greater when the initial case was paralytic than when it was nonparalytic. On the other hand, the risk of subsequent nonparalytic infection seemed to be greater when the initial case was nonparalytic. These differences were most striking among household members under 15 years of age. The attack rate among household members after the occurrence of the first case compared to that observed in the general population was greater in the nonepidemic years of 1950-1953 than in the epidemic of 1949.

Epinephrine-Mecholyl Test (Funkenstein Test): Its Value in Determining the Recovery Potential of Patients with Mental Disease. L. Alexander. A. M. A. Arch. Neurol. & Psychiat. 73:496-514 (May) 1955 [Chicago].

Funkenstein's prognostic test was administered to 201 consecutive patients prior to treatment. The results were correlated with the outcome of the therapy. The Funkenstein test consists in measuring the blood pressure changes and observing the immediate clinical and psychological response of the patient, first to an intravenous injection of 0.025 mg. of epinephrine, then to an intramuscular injection of 10 mg. of methacholine (Mecholyl) chloride. The epinephrine test allows division of the patients into two major groups—those with and those without epinephrine-precipitable anxiety. The Mecholyl test allows division of the patients into six fairly distinct groups based on their blood pressure response patterns. A seventh blood pressure reaction group is based on the epinephrine test and consists of those treatment for enuresis. Much can be accomplished by proper habit formation. Parents should realize that the basic responsibility for functional enuresis is theirs. The child's sense of security and self-confidence should be built up by loving reassurance and encouragement, rather than be destroyed by a neurotic, egocentric, emotional mother. The burden of guidance falls upon the family pediatrician or physician. He can achieve a lasting result through encouragement and a change of attitude in the child. The child should be made to void at a regular hour before bedtime. The hour of his bed-wetting should be determined, and then this act should be anticipated and the child awakened and placed on the toilet until he voids. Diet should be concerned only with the elimination of diuretics, like coffee, tea, or cocoa, and the use of nonconstipating foods. The limitation of fluids has no scientific basis. At this time the best generally available treatment in functional enuresis appears to be an apparatus that assists the formation of a normally conditioned bladder reflex. The device involves the use of a pad on which the child sleeps with knowledge and consent. If wetting occurs, a bell rings awakening the child and signaling him to go to the toilet. Later both a bell and a light were incorporated as a conditioning stimulus. The use of such an apparatus has effected cures in as high as 88% of cases.

UROLOGY

Bilateral Adrenalectomy in Carcinoma of Prostate. E. H. Ray. J. Urol. 73:712-715 (April) 1955 [Baltimore].

Ray performed bilateral adrenalectomy in six patients with advanced carcinoma of the prostate in reactivation following periods of remission after orchiectomy that ranged from 14 months to 62 months. The operation was done in one stage using a modified lateral kidney approach. There were no postoperative deaths in this group. Five patients had no evidence of osseous metastasis at the time of original diagnosis and orchiectomy with institution of estrogen therapy. The sixth had orchiectomy done elsewhere and was not seen by Ray until just prior to adrenalectomy 14 months later. In all five castration and estrogen therapy were followed by regressive change in the carcinoma, which was dramatic in one, good but not complete in two and only fair in two. At the time of adrenalectomy all of the six patients showed extensive metastasis (to bone in five and to lymphatics in one), with recurrence of bladder neck obstruction in one. All but one of the patients experienced relief from pain almost immediately after adrenalectomy, varying in degree from moderate to complete and lasting from only a few weeks in 1 to 14 months in another. Two showed no objective evidence of improvement following adrenalectomy. In four there was objective evidence of some regression. The author feels that elimination of adrenocortical function in patients whose prostatic carcinomas have become reactivated after a period of remission induced by castration and estrogen therapy will result in a second period of remission for some and marked relief from pain in most. This second period of remission with regression of the tumor will not occur as frequently as that which occurs primarily following orchiectomy nor does it seem likely to be as enduring.

Erythroplasia of Queyrat with Invasive Carcinoma and with Coincidental Carcinoma in Situ of Urethra. H. Wechsler, L. L. Spivack and A. L. Dean. J. Urol. 73:697-702 (April) 1955 [Baltimore].

Erythroplasia of Queyrat is a precancerous lesion of the penis, which is rare, and therefore often unrecognized. The case presented concerned a man, aged 59, who, when hospitalized in 1953, complained of an exquisitely tender glans penis. His lesion had first been noticed as a small, red spot over 30 years before. It did not bother him and seemed to be quiescent for about 20 years. In the next 10 years there had been a slow but steady growth. In 1947 when he had received effective x-ray therapy for squamous carcinoma of the mouth, a swelling in the right groin was also found and was diagnosed as granuloma inguinale, although Donovan bodies were not found. The Frei test for lymphogranuloma inguinale was negative. The patient was given tartar emetic, and the inguinal lesion healed in five months. He returned to the hospital in August, 1949, with symptoms sugges tive of coronary sclerosis. Physical examination of the genitali and inguinal region showed extensive scarring of the right groi and a deformity of the penis due to retraction of the prepuce A third admission occurred in March, 1952, because of pain t the glans penis. The glans was now markedly reddened a "raw." Palpation of the glans and coronal region caused muc pain. Since local treatment had no effect on the lesion or th pain, the patient was advised to undergo amputation of th penis. He thereupon left the hospital. In September, 1953, th patient entered the hospital because he could no longer tolera the pain. The lesion was bright red, irregularly circular, wi a sharp border and very tender to touch. A diagnosis of erythr plasia of Queyrat was made and the patient was again advise to have his penis amputated. He now consented. Microscopi studies on the surgical specimen led to the following diagnose erythroplasia of penis, superficially invading epidermoid carc noma of the glans near the meatus, carcinoma in situ of th urethra, and fibrosis of interstitial tissues of the penis. Nin months later the patient was still well. This case of erythr plasia of Queyrat shows the tendency to chronicity and t malignant change. Histological proof of cancer in the early lesio has never been shown, and it is likely that carcinoma started i the tissue that had been involved for many years. The findi of a separate carcinoma of the urethra is interesting, but multip cancers of the genitourinary tract have been described prev ously.

Aluminum Gel Dietary Prophylaxis After Extensive Nephroliti otomy. R. M. Spellman and V. F. Marshall. J. Urol. 73:660-6 (April) 1955 [Baltimore].

It has been suggested that the high incidence of recurren of calculi after extensive nephrolithotomy might be reduced the use of aluminum gels in conjunction with a diet low phosphate content (Shorr regimen). Further to evaluate t effectiveness of this regimen Spellman and Marshall reviewed t records of 18 patients with typical staghorn calculi in who extensive nephrolithotomy was performed at the New Yo Hospital between 1946 and 1953. In the immediate postoperati course the nephrostomy tubes were irrigated only to insure th patency. After the first week, gentle daily irrigations were us ally employed. The nephrostomy tube was removed about t 20th postoperative day. As soon as the patient was able to a general diet he was placed on the Shorr regimen. Fourte of the 18 patients were followed for growth or recurrence stone for periods varying from one to seven years postoperative In no instance did a new stone appear or a residual fragment gro while the patient was definitely following the program. In so instances defection from the prophylaxis promptly resulted a recurrence. The postoperative recurrence rate in other ser in which the regimen was not stressed has generally been hi The authors do not advocate complete nephrolithotomy in cases of staghorn renal disease. The observations from this a previous studies indicate that if such extensive surgery is ca ried out it should be followed by conscientious application the aluminum gel dietary program.

New Data on the Artificial Kidney. L. Bartrina. Presse mé 63:589-590 (April 23) 1955 (In French) [Paris, France].

Although hemodialysis with the artificial kidney has bee considered a dangerous procedure, to be used only when othe methods have failed, not a single mishap occurred in 200 patien treated by Bartrina, who believes that the artificial kidney shoul be used early in the course of the nephropathic emergency. Whe hemodialysis is performed in patients whose lesions are revers ible, the blood urea and xanthoprotein readings taken a fe hours after the completion of dialysis are lower than thos taken immediately afterward. This fact demonstrates that hemo dialysis has not only a mechanical but also a biological effec In irreversible cases (as verified by autopsy in many instance the blood urea increases after the completion of hemodialysis This phenomenon occurs presumably because, when renal fun tion no longer exists and the urea-laden blood suddenly is re placed by dialyzed blood, urea from the tissues enters the bloo in great quantities. Thus, early use of the artificial kidney, while some portion of kidney is still able to respond to the stimulus of dialysis, is of the utmost importance. Bartrina uses the technique of fractionated hemodialysis with a specially constructed apparatus allowing of bedside application. The patient has to undergo only one withdrawal and one transfusion of his own blood, which is never exposed to the air in the process. With the exercise of caution and proper sterilization, no destruction of red blood cells occurs, nor is there danger from pyrogens. Mild hyperpressure with an oxygen current oxygenates the blood and speeds the dialyzing process to one-fourth of what it was in the past. The artificial kidney should be used in all patients with acute reversible uremia, extrarenal uremia, postoperative intoxication, hepatic intoxication, shock, burns, sublimate intoxication, et cetera. The treatment is also indicated as maintenance or symptomatic therapy of hyperglycemia, blood electrolyte imbalance, rheumatism, uric hyperacidity, and chronic and progressive nephritis. In the latter category, dialyses repeated at intervals of from one to three months have proved satisfactory. Several patients have been maintained for more than a year at 0.5 to 5.7 gm. of urea per 1,000 cc., whereas they formerly had blood urea levels of 1 to 2 gm. per 100 cc. Cure cannot be obtained in these patients, but their lives can be prolonged. In uremia with reversible lesions and extrarenal uremia, the success of the artificial kidney cannot be denied.

THERAPEUTICS

Treatment of Mycotic Infections with Candida Albicans by a New Antifungal Antibiotic, Nystatine. E. Drouhet. Presse méd. 63:620-623 (April 27) 1955 (In French) [Paris, France].

The effect of a new antifungal antibiotic, nystatine, was tested in vitro on a number of strains of Candida and Geotrichum and in vivo on experimental infections in rabbits and on 35 persons with generalized or localized infections with C. albicans. In vitro, the drug was effective against all the strains, that is, 55 varieties of Candida and 5 of Geotrichum, inhibiting their growth to concentrations ranging between 1.56 and 12.5 mcg. per cubic centimeter. The drug's action was more potent in a liquid medium than in a gelose one, and it was fungicidal as well as fungistatic. The administration of nystatine to rabbits with intestinal infestation with C. albicans lessened the amount of the yeast in the intestine. The mortality among rabbits intravenously infected with C. albicans was 100%, but parenteral administration of 40 mg. of nystatine daily for five days reduced this rate to 62.5%. Massive doses (3 gm. per kilogram) of the drug introduced into the digestive tract of the animals produced no toxic effects. Nystatine was very effective both clinically and from the laboratory point of view in the 35 patients treated. Digestive and urinary disturbances cleared, and oral lesions disappeared. The organisms disappeared from, or were diminished in, the mouth, blood, stools, and urine four or five days after the administration of the antibiotic, the dosage varying between 0.2 and 1 gm. a day. Three patients had relapses about two weeks after cessation of treatment.

Urecholine in Myasthenia Gravis. H. Schwarz. Canad. M. A. J. 72:346-351 (March 1) 1955 [Toronto, Canada].

Choline esters, which resemble acetylcholine in action, have been tried in myasthenia gravis, and eventually bethanechol (Urecholine) chloride was found, which is singularly free of undesirable effects. The effects of this choline ester were evaluated on 10 patients with myasthenia gravis intermittently over a three-year period, and also in two control patients with bulbar palsy for one month. Bethanechol, when given in comparatively large doses (200 to 250 mg. daily), increased the muscle strength and significantly lessened the need for prostigmine in 9 of the 10 patients with myasthenia. Bethanechol plus less prostigmine produced a greater and more sustained increase in muscle strength than did larger doses of prostigmine given alone or prostigmine with ephedrine. Bethanechol, while in no way replacing prostigmine, appears to be a useful adjunct in the treatment of myasthenia gravis. Patients with this disease possess a remarkable tolerance for large doses of this drug. Since the completion of this report it has been found that cyanocobalamin (vitamin B_{12}), given intramuscularly in a daily dose of 1 mg., potentiates the action of bethanechol in myasthenia gravis.

Biological and Clinical Study of a Synthetic Heparin-like Substance: Dextran Sulfate. E. Donzelot, H. Kaufmann and G. Dauzier. Semaine hôp. Paris 31:1475-1480 (April 30) 1955 (In French) [Paris, France].

Dextran sulfate is a nontoxic, synthetic anticoagulant with a heparin-like action. Study of its in vivo effect on the circulation shows that it does not produce fibrinogen precipitation or platelet agglutination—the two effects by which the toxicity of other synthetic anticoagulants is most clearly demonstrated. Its anticoagulant action is sometimes superior to that of heparin, but the hypocoagulability it produces seldom leads to hemorrhagic complications. It is most effective when given intravenously, but it is also beneficial when given intramuscularly and this is often an advantage. It is well tolerated and easy to manage: the only tests needed are the Howell and Quick times and even these are not necessary unless the treatment is intensive. Some minor side-effects may be seen (e. g., allergic and vasomotor disturbances, mild diarrhea, and loss of hair in a few patients), but they are regressive and disappear either spontaneously or when treatment is suspended. The clinical effect of dextran sulfate was investigated in 60 patients with various venous, arterial, and exudative conditions and the results were found to be, on the whole, better than those obtained with heparin. Improvement occurred more rapidly and even patients resistant to treatment with heparin or a combination of heparin and dicoumarin derived substantial benefit from dextran sulfate. The venous conditions in which a favorable response was obtained included typical phlegmasia alba dolens, neoplastic phlebitis, periphlebitis, and various sequelae of phlebitis, especially postphlebitic edema. Excellent results were also obtained in arterial conditions, whatever their seat (coronaritis, chronic arteritis of the legs, certain cases of cerebral arteritis, or arterial emboli). The pain of peripheral arteritis, in particular, disappeared rapidly, and the local temperature of the affected limb increased. The only significant hemorrhage seen occurred in the one patient who showed no response to dextran sulfate; he had Buerger's disease and was in poor condition. The fact that the hemorrhage occurred although the coagulation tests were within normal limits shows that care must be used in treating patients in poor condition with dextran sulfate, no less than with heparin. The results obtained in various exudative conditions, notably postphlebitic edema, were similar to those obtained with heparin. Electrophoretic studies indicate that dextran sulfate has a more intense effect on lipids than heparin. Whether this property will prove to be beneficial in the treatment of patients with atherosclerosis remains to be seen.

On the Use of Dehydroisoandrosterone in Pilot Fatigue. G. Rotondo. Riv. med. aeronaut. 18:78-88 (Jan.-March) 1955 (In Italian) [Rome, Italy].

In many pilots, especially in some who were extremely fatigued, the author observed a syndrome characterized by asthenia, lack of appetite, dyspepsia, attacks of melancholia, apathy, hypotension, and sometimes poor general condition. Some of these manifestations are found in patients with hypoadrenia. The hypothesis that a defective or at least an altered function of the adrenal cortex was present in these persons seemed to be confirmed when an assay of the 17-ketosteroids in the urine gave subnormal values. On the basis of this finding, the author gave dehydroisoandrosterone to seven jet pilots, with from 500 to 1,100 hours of flight, in whom the above-mentioned signs were evident. In some of them aeroneurosis was present. The treatment consisted in the suspension of all flying activity, absolute rest, and prolonged administration of "Neutrostress." This preparation, which is obtained by combining 10 mg. of dehydroisoandrosterone with 5 mg. of methylandrostenediol, was given at first orally (two tablets daily), but when prompt results were not obtained the parenteral route was used. The therapy was continued for periods of 15 to 30 days alternating with treatment-free periods that varied in length according to the severity of the symptoms. A notable improvement in the subjective symptoms together with the restoration of energy and of capacity for concentration and mental work was observed after the first days of the therapy. The arterial pressure was increased slightly, some patients gained weight, and the general condition was improved. The urinary excretion of the 17-ketosteroids was increased from an average pretreatment value of 9.07 ± 1.04 to an average value of 14.37 ± 1.98 mg. These results indicate that the administration of dehydroisoandrosterone influenced the hypoadrenia, which was the main cause of the patients' illness. At the end of the treatment, all the patients except one, in whom dyspeptic disturbances were still present at the time of writing, resumed flying.

INDUSTRIAL MEDICINE

The Estimation of Health Hazards from Air Pollution. W. C. L. Hemeon. A. M. A. Arch. Indust. Health. **11**:397-402 (May) 1955 [Chicago].

In a consideration of aerosol sampling in research on atmospheric pollution and health, the principal problem is in obtaining samples of significant particle size undiluted by the omnipresent large particles of irrespirable sizes. Significant data on atmospheric concentrations apart from composition can be obtained by light scattering measurements either on filter paper or in atmospheric suspension. The available scientific data are not adequate to elucidate the question of chronic health hazards from air pollution. There is, however, no question concerning the effects of acute exposures to pollutants in the air. Fatalities and illnesses in acute smog episodes appear to be a result of simple irritation of the respiratory tract as distinct from systemic poisoning. There is much evidence to support the hypothesis that the irritant is particulate matter, whether liquid or solid, rather than gaseous. The author believes that only the water-soluble fraction in acute smog episodes contributes to the irritant effect. A study of the composition of this fraction obtained from two smog samples collected in the course of two of the most notorious episodes of acute air pollution in Donora, Pa., in October, 1948, and in London, England, in December, 1952, was carried out. Results showed that both these samples were rich in sulfates and chlorides of ammonia. It is suggested that acidic salts (in particular, metal ammonium sulfates) may be the primary substances responsible for respiratory irritation in smog episodes.

·n Spray Concentrations and Residues in Quebec Apple P. E. Braid, J. P. Windish and C. R. Ross. A. M. A. Indust. Health. **11**:408-412 (May) 1955 [Chicago].

Samples of spray mist were taken during spraying operations with parathion, and leaf and air samples were collected subsequently in three apple orchards. Sprays containing 3 to 4 lb. of 15% parathion wettable powder per 1,000 lb. of water were applied at the rate of 0.12 to 0.15 lb. of the 15% wettable powder per tree. Under low wind velocities (3 to 4 miles per hour) there was no significant concentration of parathion in the air within one hour, or more, after spraying. The authors' data indicate that with the spraying technique used in their studies, symptoms of severe parathion poisoning are not likely to occur, provided that elementary precautions are observed. Nevertheless, several cases of parathion poisoning have occurred in this area. In each case that could be investigated, it was found that some gross exposure to parathion occurred as a result of negligence. Typical of such exposures were direct skin exposure during nozzle cleaning, wearing of nonwaterproof clothing drenched with spray, or excessive skin contact with the concentrated parathion during tank filling. Thus it appears that many of the users of this insecticide have not yet been sufficiently impressed with the need for proper handling of an insecticide as toxic as parathion.

Medical and Economic Factors Relating to the Compensable Back Injury. A. S. Russek. Arch. Phys. Med. **36**:316-323 (May) 1955 [Chicago].

The compensable back injury is a special problem and differs from other industrial injuries in costs and time loss. Analyses of large groups of cases indicate that symptomatic treatment is inadequate, thereby causing many patients to present chronic problems. Early recognition of the functional diagnosis an treatment along specific, objective lines produces better results. Due appreciation of fatigue as a factor is essential understanding the patient with back pain. The term "fatigu does not refer to muscular exhaustion from overwork, but that state of muscular inadequacy associated with prolong tension without relaxation. This is apparently due to accumulated metabolites of persistent muscular contraction diminished tidal volume of blood in the tense muscles. Workin sitting, and sleeping positions are therefore extremely importa in the prevention of fatigue. There is no correct standard postu Every person should always assume the most comfortable po tion in every situation, regardless even of gross postural defect The treatment of patients with chronic back pain has five obje tives: (1) correction of posture, if possible (with corsets, brace or other mechanical devices, if necessary); (2) relief of pai tenderness, and trigger point tenderness in order to break reflex phenomena (physical therapy, local anesthesia, and/or be rest may be required); (3) release and relaxation of tense muscl (heat, massage, active and passive exercises, etc.); (4) provisio for occupational therapy under supervised conditions to p serve or develop work tolerance and work capacity as physic improvement permits; and (5) detailed instruction of the patie regarding postural habits and training for other work, if nece sary. Long-standing chronic cases present problems in rehabili tion and require intensive therapeutic teamwork.

RADIOLOGY

Cancer of the Larynx: Five-Year Results, with Emphasis Radiotherapy. C. C. Wang and A. R. O'Donnell. New Engla J. Med. **252**:743-747 (May 5) 1955 [Boston].

The authors report on 253 patients with cancer of the vo cords or the immediately adjacent structures. The group inclu patients who were registered in the tumor clinic or were s in the department of radiology at the Massachusetts Gen Hospital from 1931 to 1949 inclusive. This interval allows fo minimum follow-up period of five years. Cancer of the lar is a disease of men: 240, or 95% of the entire group were ma or a ratio of 19 men to 1 woman. Histologically all but patient had squamous-cell carcinoma. Primary radiation tr ment was given to 161, and surgery to 84 patients; 8 received treatment. The evaluation of the results was based on the st of the disease at the time of therapy. The Nielson and Strandt classification is outlined, and tables indicate the number of tients in each stage, and the results obtained with surgery radiation. Well-filtered 200-kv. x-rays with at least 0.5-m copper filter (half-value layer of 1 mm. of copper) are used satisfactory results. Two direct opposing portals with a size of 4 by 5 cm. for the vocal-cord lesions and 6 by 8 cm. more extensive disease are employed. Daily treatments are gi alternately to both sides of the neck. Estimated tissue dose 5,000 to 6,000 r are delivered to the cancer-bearing are the rate of 200 to 250 r a day, the entire course of ther covering four to six weeks. This amount of radiation sho produce a skin reaction in the form of a brisk, wet radio matitis, particularly at the anterior midline of the neck, si the two lateral portals of entry must be overlapped at this po During the course of treatments regular, frequent, indirect lar goscopic examinations are mandatory to follow the response the tumor and disclose possible laryngeal edema. The ede should be avoided, for it may narrow the glottic space and crease the radioresponsiveness of the tumor. The treatment early cancer of the vocal cords, stage 1 and 2, by either rad therapy or surgery is attended by a high percentage of succ The preservation of a useful voice should make radiotherapy treatment of choice. In advanced cancer of the larynx, stag with supraglottic extension, a trial of radiotherapy may carried out when careful observation is possible. If the dise is not controlled radical surgery is still available. In stage when remote metastases have developed, the results by rad therapy and surgery are equally poor. Even in this group, ho ever, if no cervical lymph nodes are involved, 1 in 4 patie may survive symptom free for five years after radiotherapy. T study confirmed that early cancer of the larynx is one of curable cancers.

QUERIES AND MINOR NOTES

AMINOPHYLLINE FOR MYOCARDIAL INFARCTION

To the Editor:—*It has been my routine practice to prescribe aminophylline for victims of myocardial infarction secondary to coronary thrombosis. It has been almost routine to keep these patients on a regimen of aminophylline the rest of their lives. In so doing I seem to sleep a little bit better at night hoping it may dilate their coronary vessels at least a little. I have doubted the wisdom of the prolonged use of aminophylline but would like to know what the latest trend of thought is on this subject.* *M.D., North Carolina.*

Answer.—The question of the value of aminophylline for the prevention of recurrent myocardial infarction due to coronary thrombosis is one that has never been subjected to carefully controlled critical appraisal, at least there are no completely satisfactory studies in this regard. Reports of animal and clinical studies have been equivocal in terms of dilatation of the coronary arteries. Gold, Kwit, and Otto (*J. A. M. A.* **108:**2173 [June 26] 1937) performed a double blindfold test on 100 patients to determine the effect of the xanthines on pain. Not one patient in this series could tell by his symptoms whether he was receiving aminophylline or sugar of milk. Therefore, it must be concluded that while aminophylline enjoys widespread use, the evidence is not critically validated in support of this treatment for coronary thrombosis or insufficiency.

SEROLOGIC TESTS

To the Editor:—*A woman, aged 29, who showed a negative Wassermann test in August 1954, married in September, 1954, and became pregnant. In January, 1955, three successive blood samples showed positive serologic tests (Kline, Mazzini, and Kolmer). Her husband's test is negative. No history of or signs of syphilis could be elicited, and no evidence of other disease capable of altering the complex could be determined. Ten daily injections of 1,000,000 units of penicillin were administered. Four days later the serology was still positive. How should the future course of this patient be managed?*

M.D., New Jersey.

Answer.—This may be a case of a false positive Wassermann, and it is suggested that the case be so recorded and treatment discontinued. The amount of penicillin the patient received is adequate, and, if the serology remains positive, it would be considered that the patient does not have an infection of syphilis. No further treatment should be carried out unless the patient develops clinical manifestations of the disease. The inquirer does not mention the intensity of the positive serologic tests. That may be of importance, and a weak positive test would increase the doubt of infection.

BREAST FEEDING AND POLIOMYELITIS

To the Editor:—*Is there evidence that breast feeding of infants alters the subsequent incidence of poliomyelitis?*

M.D., Pennsylvania.

Answer.—In earlier times it was a common belief that breast-fed infants were less susceptible to acute infectious diseases than those who were bottle fed. In recent years interest in the subject has been revived. Valquist and Hogstedt (*Pediatrics* **4:**401 [Oct.] 1949) state "most children receive with their mothers' milk, homologous antibodies of various types during the first few months of life." However no evidence seems to have been produced that would indicate mothers' milk may contain sufficient antibody to protect a newborn infant from poliomyelitis.

EXPERIMENTAL CORONARY ARTERY DISEASE

To the Editor:—*Some physicians say that research work done on dogs for coronary sclerotic disease is useless when these experiments are applied on human beings because dogs do not have arteriosclerosis. What is your opinion? What animals would you recommend to be used for experiments in the revascularization of the myocardium?* *M.D., New York.*

Answer.—A distinction should be made between inflow through the coronary arteries and arteriosclerosis of the coronary arteries. The arterial disease does not produce death from the disease itself. The dangerous aspects of coronary arterial sclerosis is due to reduction of blood flow through the sclerotic arteries. It is true that this reduction in blood flow cannot be produced satisfactorily by trying to reproduce the sclerotic process. However, the inflow through the arteries can be reduced by surgical methods. The method that has been used has been to carry out partial or complete ligation of one or more coronary arteries. This reduces inflow of blood and can be compared to reduction of inflow brought about by arteriosclerosis. There should be no conflict in acceptance of the experimental work on revascularization of the heart, provided this distinction is borne in mind. Vascular changes have been produced experimentally in chickens, rabbits, and dogs, but these methods are not readily applicable to the study of revascularization because the amount of narrowing of the arteries is unpredictable. The experimental work on revascularization must be controlled scientifically, and the experimenter must know how much occlusion he has produced and where the occlusion is located. Surgical methods accomplish these occlusions better than any other method.

SNAKE BITE

To the Editor:—*What is the technique of the so-called ethyl chloride treatment of snake bite?* *M.D., Louisiana.*

Answer.—A tourniquet is applied immediately and ethyl chloride is sprayed over the bitten area to the point of frost and is repeated until a bucket and ice are available. "The extremity is then immersed in ice water for from 12 to 18 hours depending on the size of the snake and severity of the bite." The tourniquet is removed after five minutes in ice water. This technique is based on the reduction of an enzymatic action by half for every 10 degrees (C) drop in temperature and is known as the "L-C" (ligature and cold) method, proposed by Herbert L. Stahnke, Ph.D. Against this treatment are the dangers of slough from unwitting freezing of the skin, vascular and tissue damage from prolonged immersion in ice water (trench foot and immersion extremity), encouragement of anaerobic growth in the wound, and formation of pseudothrombi from noncellular extravasation from the capillary bed during the warm-up period, with subsequent sloughing and tendon exposure. The tourniquet, multiple incision, and suction technique following the head of swelling is still the local treatment of choice in Crotalus envenomization. It is doubtful that ethyl chloride spray, without freezing the overlying tissue solid, would affect venom deposited at a depth of ½ in.

HOT TAR BURNS

To the Editor:—*What is the best solvent for removing tar from the skin? Frequent burns of this nature are encountered, and, other than ether, which is very unsatisfactory, I have found no good preparation for removing it.*

W. M. McBride, M.D., Alexandria, La.

Answer.—Burns as the result of hot tar can be easily cared for, usually by the use of sterile mineral oil. The application of the mineral oil makes it a simple procedure to remove the tar that is adherent to the skin. The practice is to apply the mineral oil and then to gently cleanse the entire area with soap and water and apply the usual compressive occlusion dressing.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

HORMONES FOR ELDERLY PATIENTS

To the Editor:—*The regular administration of testosterone and estrogen in people over 60 years of age is advocated by Masters and Ballew (Geriatrics* **10:**1 *[Jan.] 1955) who state that the drugs should be given in the ratio of 20 mg. of testosterone to 1 mg. of estrogen, regardless of sex (or regardless of former sex, according to the authors). The dose advised is not stated. Such medication is envisaged for the total elderly population in order to maintain both physical and mental well being. Do other endocrinologists have precise information about this? What is the exact dosage? Are these hormones taken regularly apt to be cancer producing?*

M.D., Georgia.

Answer.—There is no quantitative data on the dosage of testosterone and/or estrogen in the elderly patient. The average male (up to 50 years of age) utilizes about 50 to 75 mg. of testosterone propionate weekly. The menstruating female utilizes about 1 mg. of stilbestrol equivalent daily. From clinical experience, the oral combination of androgens and estrogens affords anabolic synergism in dosages smaller than if either hormone is used alone; such combinations neutralize each other's influence on genital tissues, thus preventing masculinizing or feminizing symptoms. Both androgens and estrogens normally occur in both sexes, but in different quantities, as ascertained indirectly by comparison of urinary estrogens, androgens, and 17-ketosteroid excretions. No single androgen-estrogen preparation is suitable for all patients. There is no evidence that either testosterone or estrogen will produce cancer; however, routine examinations should be made with particular reference to the genital tract and breasts in women and to the prostate gland in men prior to instituting androgen-estrogen therapy. If malignant disease exists, or is suspected, a combination of androgen-estrogen therapy is contraindicated.

ACCURATE CHLORIDE DETERMINATION

To the Editor:—*Please describe and evaluate the urinary test for estimation of degree of adherence to sodium deprivation regimen.* *Luther Newhall, M.D., Santa Cruz, Calif.*

Answer.—For accurate scientific purposes, sodium must be determined directly. This is a task for a trained chemist, generally using a flame photometer. Since analyses of electrolytes in blood are gaining increased importance, a growing number of hospitals are acquiring this apparatus. The question seems to refer chiefly to the practical need of checking dietary control by a busy physician. This problem may pertain to gross violations of diet or to small errors. Chloride estimations are then depended on for indirect calculation of sodium values. The crudest check, in office or at bedside, requires only one solution containing 1% silver nitrate and 2% nitric acid and another solution containing 0.5 gm. of pure sodium chloride per liter. Any protein in the urine is removed by acidification with acetic acid, boiling, and filtering. Small equal volumes of urine and sodium chloride solution are placed in similar tubes, and an equal number of drops of silver nitrate solution are added to each. The density of the resulting white cloud in the tubes is compared. Either the urine or the sodium chloride solution may be diluted until the precipitate in the two appears equal, and simple arithmetic then gives the approximate percentage in the urine. The majority of dietary errors are gross enough to be revealed by this simple test. For more accurate chloride determination, the Whitehorn modification of the original Volhard silver nitrate titration is described in laboratory manuals and is usable in an office or small laboratory. A simplified office or bedside quantitation was described by Bryant, Job, Phillips, and Blecha (*J. A. M. A.* **140:**670 [June 25] 1949). It calls for only two solutions, namely a 10% solution of potassium chromate and an 0.73% solution of silver nitrate. Both may be kept in dropper bottles, the latter in dark glass. With another dropper, 10 drops of urine are placed in a Kahn type of test tube. Add 1 drop of potassium chromate, and shake. The silver nitrate solution is added drop by drop, with shaking, to the end-point of a permanent light brown or brick red color. Each drop of silver nitrate used represents approximately 250 mg. of sodium chloride or 100 mg. of sodium per liter. Estimation of sodium by means of chloride rests on the assumption of excretion almost exclusively in the form of sodium chloride. Two main fallacies must be guarded against; first, the ingestion of sodium bicarbonate or other nonchloride sodium salts; second, the presence of other chloride or halogen salts, such as bromides, or particularly the potassium chloride, which is an important constituent of salt substitutes in the diet.

CLICKING IN EAR

To the Editor:—*A patient has had head noises, loss of hearing, and a rather bad postnasal drip since the age of 20. Ten years ago a fenestration of the semicircular canals was performed. The patient now experiences a clicking in the ear that was operated on, especially when he swallows. The clicking starts about 7:30 p. m. and is very bad at night, when the patient is lying down, and in the morning. There is little clicking during the day. During the times of the clicking, the patient experiences no pain. At night, when the clicking starts, the patient has developed a compulsion to swallow. What is the cause and treatment?* *M.D., New York.*

Answer.—Clicking sounds in the ear may originate from three possible sources. First, there may be an abnormal amount of sticky mucus in the eustachian tube and over the torus. When the levator and tensor veli palatine muscles are tensed, as in swallowing, this action may form a film that, on breaking, may produce a clicking sound. Second, a rhythmic tic of the above muscles may be present, producing a rhythmic sound. This can be identified easily by observing rhythmic contractions of the palate on the involved side. Third, clicking sounds in the ear have been observed to persist after bougienage of the eustachian tube. It has been thought that this may be secondary to an injury to the tensor tympani or its nerve supply. These types of ear noises usually are not amenable to treatment, although sedatives may be tried. Fifty milligrams of chlorpromazine hydrochloride given three times a day might be suggested. Postnasal drip probably would not have causal significance in association with this symptom.

DEATHS DUE TO RABIES

To the Editor:—*Please give information on the human death rate due to rabies, as in our group none of us have ever seen a death due to this cause.*

L. G. Hunter, M.D., Milan, Ind.

Answer.—The following tabulation shows the United States death rates from rabies, 1932 through 1952.

Yr.	No. of Fatalities	Yr.	No. of Fatalities	Yr.	No. of Fatalities
1932........	55	1939........	40	1946........	34
1933........	65	1940........	41	1947........	26
1934........	80	1941........	39	1948........	24
1935........	77	1942........	36	1949........	10
1936........	73	1943........	47	1950........	18
1937........	59	1944........	56	1951........	18
1938........	66	1945........	43	1952........	24

DISEASES EXHIBITING SEASONAL INFLUENCE

To the Editor:—*Would you furnish an extensive list of diseases with a seasonal incidence.*

Joseph E. Moylan, M.D., Scranton, Pa.

Answer.—To list all diseases exhibiting a seasonal influence would mean setting down most of those carried in the "International List of Causes of Death." Perhaps it would be more appropriate to point out certain broad categories of disease in which the seasonal influence is strong. These are infectious and allergic diseases of the skin and respiratory and digestive systems, contagious diseases of childhood, metabolic diseases, and arteriosclerotic and coronary heart failure. The one broad disease category not yet shown to be influenced by season is that covering all classes of malignant disease, but even here there is a strong climatic or latitude influence.

EXACERBATION OF OLD TUBERCULOSIS

To the Editor:—*A white woman, aged 71, had in April, 1954, an acute flare-up of a pulmonary tuberculosis, which had been quiescent for 20 years. It started with an acute illness, with high fever, cough, and extreme prostration. The condition cleared up within a week under treatment with aureomycin. However, a lasting weakness and some cough remained. Sputum was positive for tuberculosis, and x-ray examination revealed right apex contracted with dense fibrosis at first and second anterior interspaces and irregular highlights (cavitation?). The density reaches from the apex down to the upper hilum. The superior mediastinum is shifted to the right, with distortion of the lower trachea and the main bronchus. The left apex also shows fibrotic changes. The left dome of the diaphragm is elevated, flattened upwards with thickened basal pleura. X-ray diagnosis shows moderately advanced, bilateral pulmonary tuberculosis. Strict rest in bed was ordered, and biweekly treatment with doses of 2 cc. of streptomycin intramuscularly with three oral doses of 125 mg. of nydrazid daily were given. The cough was very mild, temperature was normal within two weeks, and the sputum and the inoculated cultures of it became after six weeks consistently negative for tuberculosis and remained so until today. This treatment had been continued without interruption for nine months, and the patient has gained weight. She only feels a little weak on her feet but moves around in her rooms. How long should streptomycin-nydrazid treatment be continued?*

M.D., New Jersey.

Answer.—The description of the findings is quite clear, and there is little doubt about the diagnosis of the exacerbation of the old tuberculosis as well as the acute onset that was probably due more to a bacterial process rather than to a virus since aureomycin was so effective. At least the predominant factor causing symptoms was probably one of the virulent cocci. This type of tuberculosis is one that usually responds poorly to antimicrobial therapy. The vegetating acid fast bacilli were soon eliminated by the treatment, but there were probably many tubercle bacilli that were in a state of "hibernation" in the old fibroid lesions, during which time the bacilli seem to be little affected by the drugs. When the condition of the patient becomes worse, many of these "sleepers" start to grow and the disease becomes reactivated. That is a theoretical reason for a long continued course of treatment for nine months or a year more. At the end of that time, a reevaluation of the case may be advisable to see if still more therapy is indicated. The treatment followed has been proper. At this time it would be well to use 1 gm. twice a week of dihydrostreptomycin instead of streptomycin to avoid the possibility of damage to the labyrinth. Also it would be well to begin a plan of graduated exercise. Antimicrobial treatment has permitted some shortening of the rest periods over the old-time rest regimens but not too much. There should never be any symptoms produced by the exercise schedule, and the patient should not be allowed to think he, or she, is as well as he may feel. The feeling of well being is sometimes out of all proportion to the true condition.

ALOPECIA AREATA

To the Editor:—*Can you explain the sudden appearance of two bald spots in the scalp of a normal and unusually vigorous 5-year-old girl, who has had no antecedent scalp or constitutional disease? The rapidly developing bald plaques show an entire absence of hair, and they are sharply defined, whitish in color (with a smooth consistence), circular in shape, and of the size of 25-cent and 50-cent coins.*

M.D., California.

Answer.—The youngster apparently has alopecia areata, a condition that is but little understood. Emotional factors in some indirect manner are thought to play a causative role, but the connection has not been proved. The treatment is one of stimulation to the scalp, either by hand massage, electric apparatus, ultraviolet rays, or application of a stimulating ointment. The condition sometimes corrects itself without treatment.

GIVING FOOD DURING A TRANSFUSION

To the Editor:—*There has been a controversy in a local hospital about allowing patients to receive food while receiving blood by transfusion. Is there any reason why this may be harmful? In some instances blood is given slowly, and two or three hours may elapse during which patients requiring nourishment would be deprived of it. I am aware of passive transfer of sensitization, as in the case reported by Ramirez some years ago. It seems that conditions existing in the donor are to be guarded against, and this is usually done in the collection of blood for blood banks. I have found nothing in works on blood groups and transfusion concerning not allowing patients to receive food during routine transfusions, but, as there has been some criticism of the practice, I would like to have the matter clarified.* *M.D., Illinois.*

Answer.—In most cases the recipient of a transfusion receives blood as a necessary restorative measure during a period of one to three hours, and the necessity of feeding during this time is not even considered. Actually the patient's system is not being starved, since plasma containing glucose, salts, and nutriment is being received intravenously. Where the transfusion is given as an elective procedure rather than as a measure of urgency and more than two or three hours may elapse, if the patient complains of hunger it seems advisable to give a light meal of easily digested foods such as milk and crackers or a sweet drink merely to appease the appetite during the period of transfusion. The question raised of allergy passively acquired from the donor and precipitated by taking the allergen in food while the transfusion is being given is theoretically valid. Questioning the donor about his allergic reaction and not taking blood from a highly allergic donor is good blood bank practice. One other point should be borne in mind. If the blood is injected rapidly, particularly in a sick, very anemic patient and one with possibly partially decompensated cardiac disease, the patient should not be given large amounts of salt solution intravenously nor heavily salted food by mouth lest the intake of a considerable amount of sodium at such time produce pulmonary edema. This is a hazard of transfusion too often ignored or not recognized. In general the administration of food during a transfusion is not practiced and should be avoided except as suggested above.

CHLORINATED HYDROCARBON INSECTICIDES

To the Editor:—*Do any of the chlorinated hydrocarbon insecticides increase the activity of phosphatase enzymes? Do they cause an imbalance in the hormone production of the eosinophils and basophils of the pituitary, thereby causing anatomic and physiological changes throughout the body? Through their influence on the hypothalamus will they produce or aggravate conditions that are benefited by Rauwolfia drugs? Will they imbalance the enzyme activity in the steps of "Kreb's cycle" and produce or aggravate such clinical conditions as poliomyelitis, cancer, and kwashiorkor?*

George C. Furr, M.D., Clarksdale, Miss.

Answer.—Whether one considers a single large dose or repeated small doses, even the most casual observation indicates that the chief action of chlorinated hydrocarbon insecticides is on the neuromuscular system. The most careful study has shown that these compounds alter the function of every part of that system that has been suitably studied—cerebrum, cerebellum, cord, sensory nerves, motor nerves, autonomic system, and muscles. The basis of this action is unknown, but studies in several laboratories have apparently ruled out the possibility that it depends on an alteration of cholinesterase activity, oxygen consumption, or a variety of other reactions of nervous tissue. Our state of knowledge concerning these insecticides is, therefore, very similar to the state of our knowledge of many drugs that act on the nervous system. Minor inhibition of some enzymes of various tissues, activation of other enzymes, and no effect on most enzymes has been reported. In no instance has the magnitude of the effect been sufficient to explain the action of the compounds or to cause any significant physiological effect. It should be remembered that tissue enzymes usually have to be depressed to a small fraction of their normal activity before any change is produced in the function of the intact body.

No effect of chlorophenothane (DDT) on the hormones of mammals has been demonstrated, but large doses of chlorophenothane do act, through an unknown mechanism, to retard testicular development in cockerels. There is good reason to continue the search for the mechanism by which effective doses of chlorinated hydrocarbon insecticides produce their observable actions; this tedious, time-consuming work is going forward. In the meantime, a different sort of study has been carried on with chlorophenothane that should do much to allay fears and idle speculation. It has been shown that human beings who have voluntarily taken daily, for nearly a year, about 200 times the amount of chlorophenothane that appears in the average diet suffered no ill-effects that they could detect or that were revealed by careful physical examination and laboratory tests. These men absorbed more chlorophenothane than pest control operators or farmers who use the compound. The other chlorinated hydrocarbon insecticides are produced and used in smaller tonnage; they will be investigated as opportunity permits. As to the relation of chlorinated hydrocarbon insecticides to poliomyelitis, cancer, and a wide range of other diseases, Fowler (*Agric. Food Chem.* 1:469, 1953), who studied agricultural workers who used insecticides, said, "No evidence could be found that pesticides were the direct or indirect cause of any chronic disease, nor a contributing cause in diseases generally recognized as having other etiologies."

ABSINTHE

To the Editor:—*I recently learned there is an alcoholic beverage called Absinthe banned for sale or consumption in this country, presumably because it produces a nervous disorder by prolonged use. What is it composed of, and what is the pathogenesis of the disease it produces?*

Edward F. Blasser, M.D., Miami Beach, Fla.

Answer.—Absinthe differs from other alcoholic beverages in that it contains an extract of wormwood. Extract of wormwood in rabbits caused dyspnea, hematuria, gastroenteritis, and death. The volatile oil is an active narcotic poison causing trembling, stupor, and later violent epileptiform convulsions with involuntary evacuation, unconsciousness, and stertorous breathing that may end in death. One-half ounce of the volatile oil consumed by a male adult caused insensibility and convulsions with foaming at the mouth, although he recovered under the use of emetics with stimulants and emulsives. The effects of Absinthe differ from those of ordinary alcohol in that the characteristic symptoms of the former are restlessness at night, disturbing dreams, nausea and vomiting in the morning, trembling of hands and tongue, vertigo, and tendency to epileptiform convulsions.

TOOTHPASTE

To the Editor:—*What is the value, if any, of the "magic ingredients" now being added to practically all brands of toothpaste?* *C. Jay Hoyt, M.D., San Francisco.*

Answer.—The principal value of these ingredients may be in sales appeal. At this date the Council on Dental Therapeutics is not aware of adequate evidence that these ingredients are of substantial value in dental caries prophylaxis. Brushing the teeth with a suitable brush and dentifrice immediately after eating reduces residual carbohydrate, which is an important factor in tooth decay. Further benefit from a specific ingredient is doubtful in presently available products.

INFANT'S TOLERANCE FOR MILK

To the Editor:—*In the allergic infant with eczema, how long a period of abstinence from milk is required to establish tolerance for this food?* *M.D., Massachusetts.*

Answer.—The majority of such infants develop a tolerance even without eliminating the food. Abstinence from it probably results in more rapid and more certain tolerance. The time required varies not only with the degree of sensitivity but with other unknown factors. In the average case it could take several months.

COLORED MOVING PICTURES

To the Editor:—*Several patients, while wearing proper
scription glasses, have noted blurring of vision when view
colored movies on the new wide-angle screens. The pic
looks clear when they remove their glasses. Blurring does
occur when viewing black and white movies. What is the c
of this phenomenon?*

M.D., Ohi

Answer.—There is no adequate explanation for the
nomenon described on a basis of refraction. Certainly, the di
ence in refraction of the red and green components of the
ture cannot explain the blurring, when as stated the scre
seen clearly in black and white. These individuals probably
strongly with accommodation under these circumstances
probably produce a pseudomyopia, thus explaining the bl
vision. This complaint must be extremely rare since so
people observe moving pictures in color and in black and
and the complaint described has not appeared in the litera

MONOMER GASES

To the Editor:—*I must call your attention to a misinterp
tion of my publication that appeared in* The Journal (1
*[May 7] 1955), under the heading Monomer Gases. A
bottom of the second column I was quoted as reporting
4,000 ppm of chlorotrifluoroethylene killed 50% of a
of animals when inhaled four hours daily for 14
Actually the article* (J. Indust. Hyg. & Toxicol. **31:***343 [
1949) refers to single four-hour inhalations of a wide v
of vapors followed by 14 days of observation without fu
vapor inhalation. Therefore, the 1949 article referred
single four-hour inhalation, not to the 14-day repeate
halation given by your correspondent. The work done in
was on a pilot plant product. Work in 1954 on chlorotrifl
ethylene made on a commercial scale showed a greater d
of toxicity. Within 14 days of one four-hour inhalatio
rats died from 1,480 ppm; none died from 710 ppm,
severe kidney pathology was found; and none died from
ppm, and there was no kidney pathology.*

CONSIDERATIONS IN THE PREPARATION AND USE OF POLIOMYELITIS VIRUS VACCINE

Jonas E. Salk, M.D., Pittsburgh

In assessing the state of knowledge of any subject a particular point in time, it is as important to define at is not known as it is to appreciate what is known. is for this reason that I would like to discuss some the problems still before us, with respect to vaccinan against poliomyelitis, as well as to review knowledge ned in the course of recent work. "Can durable imnity be induced by a noninfectious poliomyelitis vace?" is one of the principal questions still to be anered. Since the ultimate answer to this question cant be obtained until time has passed, we must content rselves only with an examination of facts now known, m which we can make some tentative interpretations m the trends observed.

The hypothesis that the presence of neutralizing antidy in the circulating blood is an effective barrier in lucing the likelihood of paralysis by the poliomyelitis us is now well supported by the great volume of inect, as well as direct, evidence from studies in exrimental animals and in man, on passive and active munization.[1] In this discussion, therefore, I will exine the evidence that exists concerning the creation of tibody and also the persistence of antibody induced tificially by vaccination.[2] Observations in some, of any more, individuals who were vaccinated one and half years earlier, and others vaccinated two and a half ars earlier, will be shown. I will try to orient my rearks along practical lines but will do so principally by ference to the theoretical and experimental considerations upon which are based the preparation and use of poliomyelitis vaccine.

To begin a discussion such as this, from the practical viewpoint, it would be well to consider first the special attributes required of a poliomyelitis vaccine, as compared to vaccine for any other diseases, since a vaccine for poliomyelitis requires particular attention as regards both safety and effectiveness. We know only too well the uniqueness of paralytic poliomyelitis, among all of the *infectious diseases*; the unusual combination that exists here is the terror and tragedy inflicted to a degree that is out of all proportion to the frequency of attack. The relative infrequency of severe paralysis under natural circumstances requires, above all else, that the vaccine must be free, insofar as it is possible to create such a preparation, of the capacity to induce the disease that it is intended to prevent; nor should a vaccine for poliomyelitis cause such side-effects as would make its use undesirable. If either the direct effects associated with its use, or incidental side-effects to any constituent, are of such nature as to make one prefer the chance of escaping the paralytic disease, one would not have a practically useful immunizing agent.

PRINCIPLES OF VACCINE PREPARATION AND SAFETY TESTING

First, I would like to describe the principles upon which the preparation of poliomyelitis vaccine is based and, particularly, the considerations involved in testing

for safety. The objective in the preparation of a poliomyelitis vaccine cannot include the knowing or willful acceptance of a risk that is tangible, or measurable to any degree. Any risk that is involved, so long as it is recognized, must be corrected, whatever may be its cause; in the preparation of experimental vaccines in our own laboratory, and on a larger scale for field trial, it was the factor of safety, above all else, that imposed the limitations in the rapidity with which our studies were progressively advanced. To permit the practical application in the field to come close upon the heels of the rapid advances that were being made by investigations in the applied aspects of the problem, rather extensive transformation and expansion of the various facilities necessary for the availability of vaccine was required.

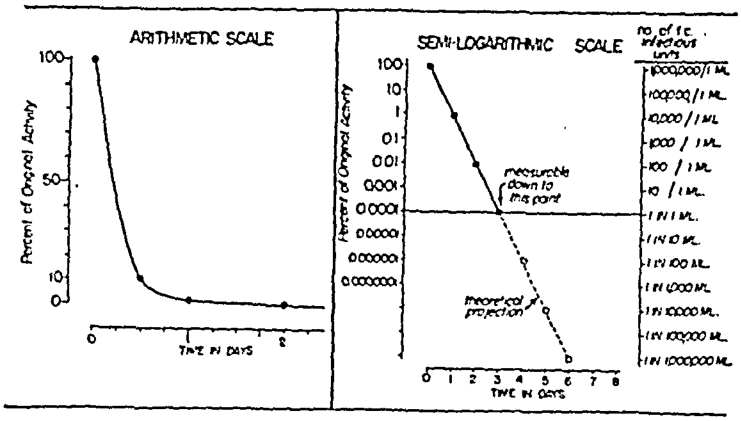

Fig. 1.—Rate of destruction of poliomyelitis virus infectivity at 37 C in presence of 1:4,000 formaldehyde solution (Formalin) at pH 7.

Although there were no indications either from our own studies in some 15,000 children, or from the much larger experience in the field tests of 1954, that the vaccine preparations employed contained infectious virus, it is understood now generally that certain lots of vaccine used in April, 1955, were associated with the subsequent development of paralytic poliomyelitis. This demanded a very intensive reexamination of the theoretical and practical implications of vaccine preparation, testing, and use.

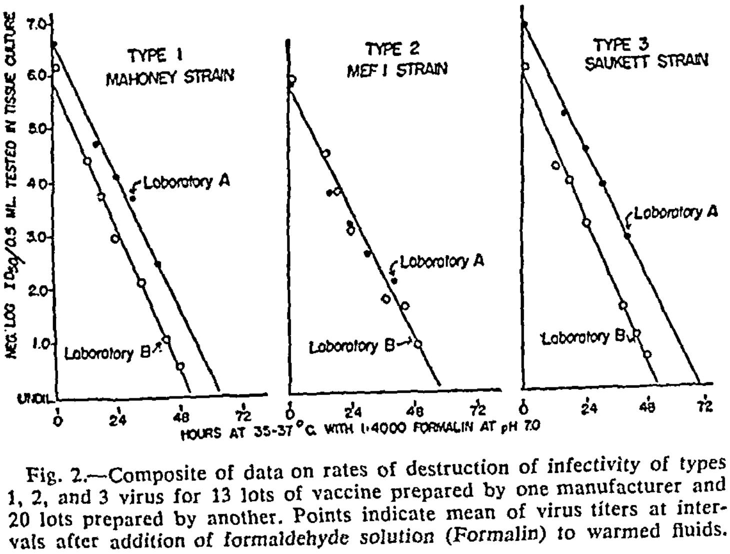

Fig. 2.—Composite of data on rates of destruction of infectivity of types 1, 2, and 3 virus for 13 lots of vaccine prepared by one manufacturer and 20 lots prepared by another. Points indicate mean of virus titers at intervals after addition of formaldehyde solution (Formalin) to warmed fluids.

I might say at this point that my own evaluation of the recent reexamination of the manufacturing and testing processes suggested a need for adjusting the techniques employed for large-scale operations so as to approximate that which it was possible to accomplish on an experimental basis; the objective is to yield the consistently satisfactory preparations that it has been possible to achieve, not only in the laboratory but even on a large scale. The theoretical considerations that applied originally are still sound and applicable—what is required is closer approximation in practice. I would like to discuss the theoretical considerations first and then to show how the practical problems have been, and are being, met.

It has been realized always that the preparation of a safe poliomyelitis vaccine would, at the beginning at least, require adherence to detail such as is not demanded for the preparation of any other immunizing agent. It was recognized, too, that there must be incorporated into the vaccine preparation process itself a test for safety, which we refer to as "the margin of safety," of such degree that the most sensitive tests upon a sample of each successive batch would be negative for living virus unless something unexpected had occurred, unknowingly, in the process of manufacture, or in subsequent handling, or in testing; it would follow that such would not be expected to occur but rarely. To help in knowing where the difficulty might have occurred in any given instance, tests are needed at various steps in processing, including the final stages. A series of observations, both in our laboratory and in the laboratories of manufacturers of biologicals, indicated that the desirable objective of consistency in reproducibility of vaccine preparation with an adequate margin of safety could be achieved.

* Symbols indicate whether finished vaccine met all criteria for safety. — = no, + = yes.

In the early phases of our investigations it was necessary, in exploratory experiments, to determine the nature of the reaction between formaldehyde and poliomyelitis virus,[3] using various concentrations of formaldehyde, different temperatures, and different degrees of acidity. The conditions selected for preparation of field test vaccine were those that would lend themselves most readily to large-scale adaptation in a way that would provide the desired margin of safety not only with respect to th

estruction of virus infectivity but also with respect to e retention of antigenicity. Such studies furnished the rinciples upon which a carefully controlled inactivation rocess could be developed for use in the laboratories of ny producer of biological products that could acquire e staff and facilities for making poliomyelitis vaccine.

I can best illustrate what I mean using the accompany- g figures, which show the generally expected behavior, ased upon experience with experimentally produced accine. The left-hand portion of figure 1 shows that vithin the first 12 hours after the beginning of chemical reatment, 90% of virus infectivity is destroyed; within he subsequent 12 hour period, 90% of the infectivity hat still remains is destroyed—or, about 99% of virus nfectivity is eliminated within the first 24 hour period; n 48 hours, approximately 99.9% of the original infec- ious activity is obliterated. To eliminate the last traces f infectivity to a point below which none can be detected equires continuation of treatment for a number of days onger. From the practical viewpoint, the question that iad to be answered was, "At what point may it be pre- umed that virus infectivity is destroyed, either totally r, at least, to a degree beyond which it can no longer be neasured and, therefore, can be presumed not to be harmful to man?" The right-hand portion of figure 1 illustrates further the data depicted on the left, but in another way—that is to say—on a semilogarithmic scale, which allows a more precise examination of the portion of the left-hand curve that is in the range below 1% of remaining infectivity. Here it may be seen that in the course of three days the infectivity for tissue culture of material being converted into vaccine has been so altered that, whereas originally it contained one million tissue culture infectious units per milliliter, at the end of the first three-day period, there remained but one tissue culture infecting unit per milliliter. If treatment is continued for not less than an additional six days, it is expected that with thorough mixing of virus and formaldehyde, the maintenance of uniform temperature, a reasonably homogeneous population and adequate dispersion, the material treated for a total of nine days or longer should, theoretically, be free of any demonstrable virus—even if all of the fluid being converted into vaccine were tested in tissue culture or even in man. Such experiments were done under the conditions that apply not only in our laboratory but on a large scale in other laboratories in this country and abroad (fig. 2 and table).

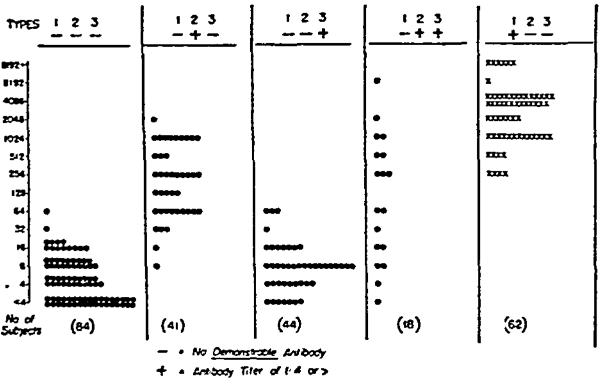

Fig. 3.—Type 1 antibody response to first dose of vaccine in persons with different prevaccination antibody patterns (vaccine lot 309). Different prevaccination antibody patterns are indicated at the top of each column.

The critical factors that influence the slope of the line in the right-hand portion of figure 1 are (1) temperature, (2) formaldehyde concentration, and (3) pH. Since the amount of free formaldehyde will be influenced by such constituents as the protein content, or the concentration of free amino acids, then constancy of composition of the fluid being converted into vaccine is a factor that would affect the rate of reaction. In spite of our ability to control these variables within practicable limits, it is still necessary to ascertain, by suitable tests, that all of the considerations have, in fact, been properly effected. There is one critically important factor that demands close attention and that is the matter of uniform mixing; another is the use of such techniques that reduce, if not eliminate, risk of recontamination with live virus. Failure to mix adequately will introduce such uncontrollable variables as may be described by the term "fractional

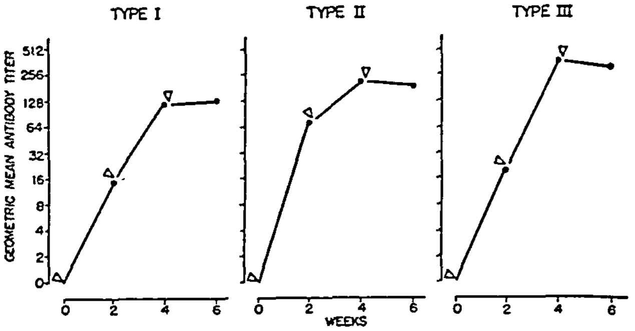

Fig. 4.—Geometric mean titers after each of three doses of reference vaccine "A," 1 ml. given intramuscularly to 20 subjects with no pre-antibody to any type.

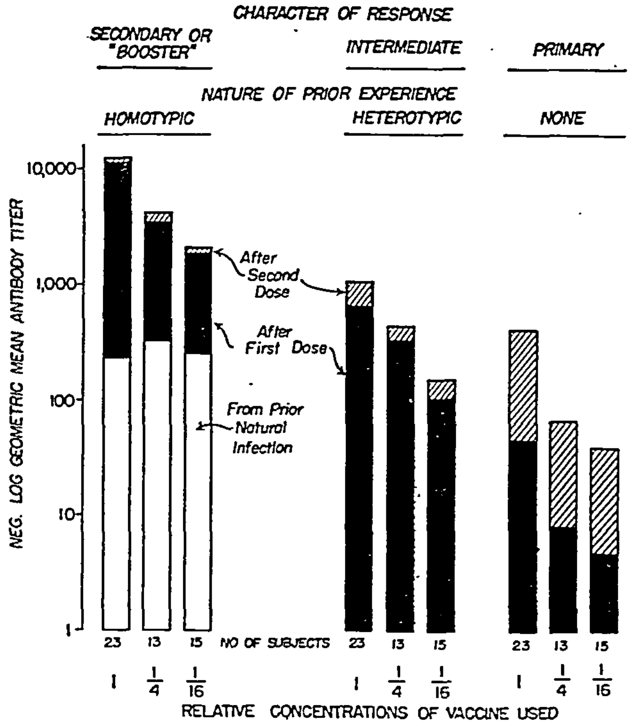

Fig. 5.—Different patterns of antibody response, depending on nature of prior immunologic experience, after two doses of reference vaccine "A" given two weeks apart, with blood drawn two weeks after each dose.

inactivation," and this may make it appear that resistant particles are present. Another factor is the use of filtration procedures to remove particles that might interfere with inactivation. As has already been mentioned, a check for any deviation from the expected is made by tests upon suitable samples removed at particular stages in the course of processing.

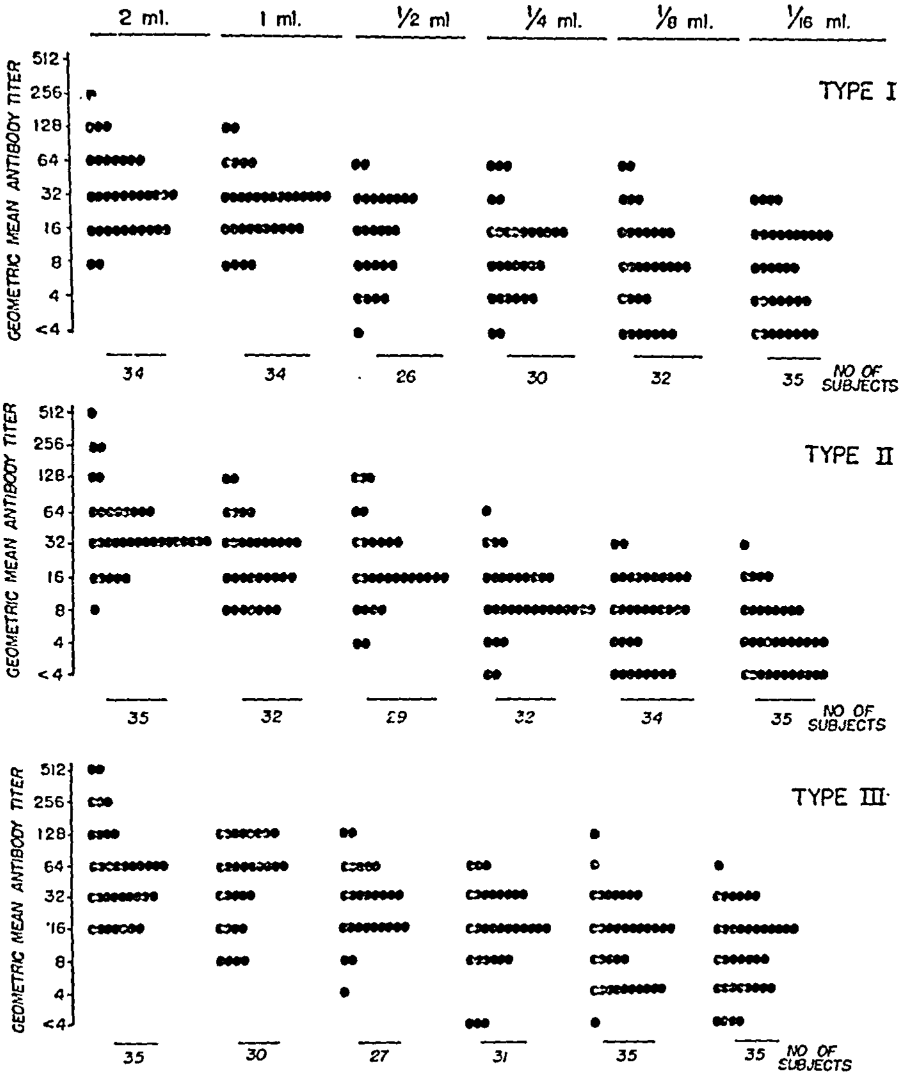

Fig. 6.—Dosage effect: Type 1, 2, and 3 antibody response two weeks after one dose of reference vaccine "A" given intramuscularly to subjects with no demonstrable preantibody to any type.

In the critical review that was made recently of the requirement for manufacture, tests were specified at two additional check points in the process, and the volumes of fluid to be tested at each step for each batch were set at fixed quantities. In addition, failure of a batch to be inactivated in the expected time would preclude its being reprocessed, and it is required that such batches be discarded. This is merely in conformity with the present requirement that there be demonstrated an adequate margin of safety for each batch of vaccine. The details that have been spelled out merely define what is meant by adequate margin of safety and in actual practice are further reinforced by requesting compliance with the original requirement that there be satisfactory consecutive experience of each manufacturer in being able to produce vaccine consistently free of living virus, and with the desired margin of safety.

It may be said that the design of the inactivation process, for the experimentally produced vaccine and for larger scale preparations, was intended to provide a quantitative expression of margin of safety. This was based upon the opinion that the testing merely of a sample of the final preparation, as is customarily employed for most biologicals, was inadequate for the special needs of the vaccine under consideration.

But there are still many other technical aspects of the broad problem upon which investigations will continue for a long time to come. One of these is in regard to the particular strains of virus for the most effective vaccine. Th strains selected for our very first studies wer chosen because, among many from which selec tions were made, these produced the highest in fectivity titers in tissue culture and were als shown to be highly antigenic in monkeys an man. It has now been found that, within broa limits, high infectivity and high antigenic p tency are not necessarily associated, and, in fac they are independent properties. These tren emerge from a series of investigations in whi strains are being selected that are among t most potent antigenically, and from among the we will select those that are of low pathogenic for monkeys when administered by periphe routes. The principle objective of this phase our studies is to incorporate in the vaccine type 1 strain that has the same attributes of h antigenic potency as do the MEF-1 strain type 2 virus and the Saukett strain of type that appear to be more potent antigenically t does the Mahoney type 1 strain; and while do so, to select one of low peripheral pathogeni for monkeys. But the latter is only a second consideration, since the first requirement t must be satisfied regardless of strain is that i rendered noninfectious for man. In studies w laboratory-selected variants that are aviru some are very poor antigens whether they used in their fully infectious form or after in tivation with formaldehyde solution (*Forma* This is something of considerable theoretical and p tical interest.

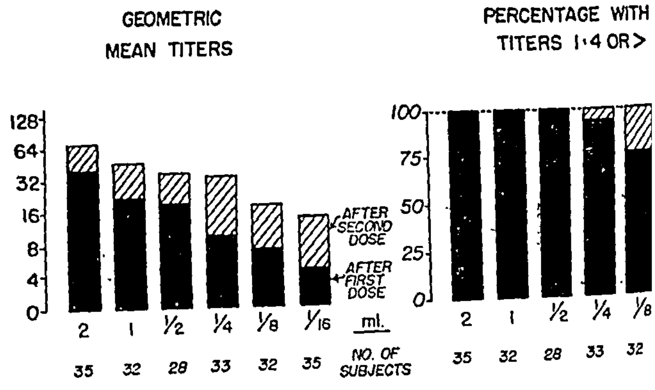

Fig. 7.—Type 2 antibody response two weeks after two do reference vaccine "A" given two weeks apart.

IMMUNOLOGIC FACTORS INFLUENCING VACCIN EFFECTIVENESS

The question of vaccine effectiveness is, of co secondary to the question of vaccine safety. I w therefore, like to discuss now the question of vaccin tiveness. Here we have two distinct issues: (1) the nediate one—the immune response that can be ex- ted after each of the three doses of vaccine, and (2) that arises later—regarding the degree of persistence immunity after the third inoculation. There is the fur- r question of the spacing and frequency, if later inocu- ons are required.

rimary Vaccine Response.—The various factors that uence the primary response to vaccine are illustrated a series of figures to follow. The first point that I wish make is that antibody response is influenced by prior munologic experience. For example, an individual o has not had any prior poliomyelitis virus infection cts quite differently to vaccination than does an in- idual who has had an infection with one or more of se viruses. This is illustrated in figure 3, where it may seen that the antibody response to the first dose of a atively poor vaccine was quite different in persons o had no previous immunologic experience as com- ed with those who had a prior infection with either e 2 or type 3 virus, or both; it is to be expected, of rse, that there will be a very different pattern of re- ivity if there has been a prior homotypic infection, ., type 1 in this instance. It should be clear from these ta that, from a practical point of view, it is necessary know the nature of the antigenic response in persons ho have had no prior immunologic experience if one to make valid comparisons concerning the nature of the influence of vaccine potency, time, and spacing of inoculations, and any other questions that can be answered only by the application of quantitative immunologic methods. It is for this reason that I will confine this presentation, except as necessary, to make a particular point, to data derived in studies in children who had not had any prior experience with any of the poliomyelitis viruses.

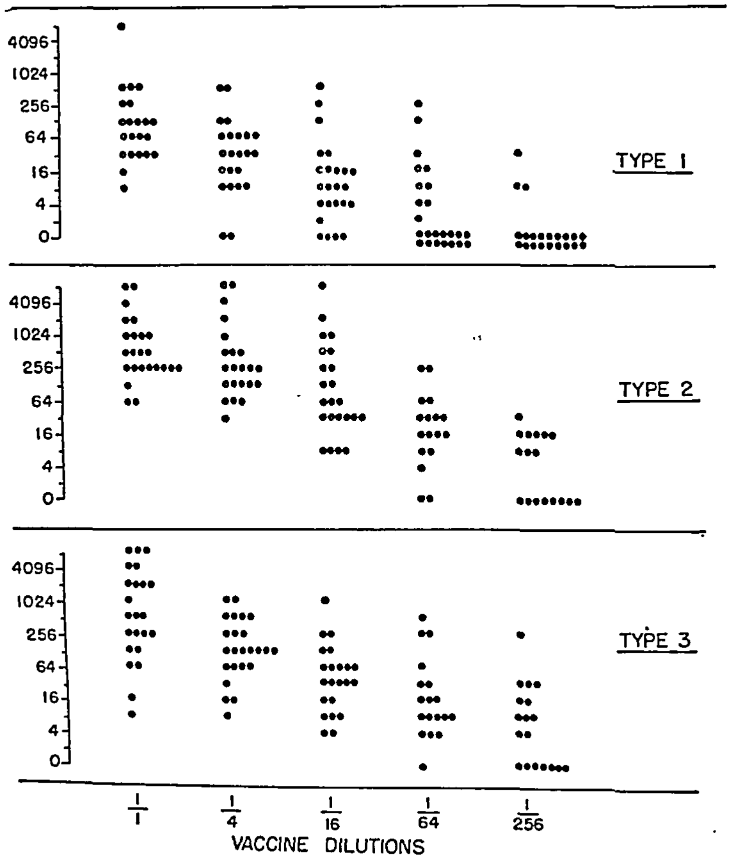

FIG. 11

Fig. 8.—Antibody response in groups of monkeys vaccinated with diminishing dilu- ns of reference vaccine "A" given in three doses intramuscularly, 1 ml. each week one ck apart, with blood drawn one week after third dose.

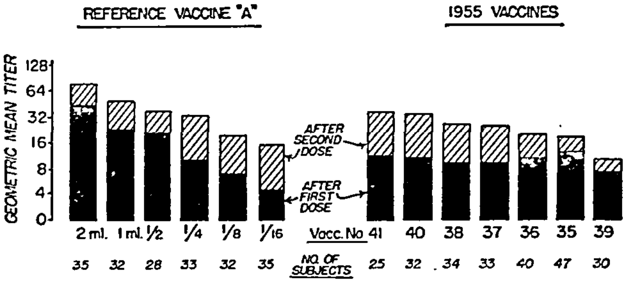

Fig. 9.—Comparison of seven lots of 1955 vaccine with reference vaccine "A." Type 2 response two weeks after two doses given two weeks apart.

Figure 4 illustrates the degree of antibody response after three doses of vaccine given to a group of children who prior to vaccination had no antibody to any of the three types. It is clear from this chart that a substantial response occurred after the first dose of vaccine, a moderate increase occurred after the second dose, but little or no increase occurred after the third dose when the three doses of vaccine, of the potency used here, were spaced with an interval of two weeks between each. The reason for the suggestion that the third dose should be postponed is indicated by these data, and the reason for the suggestion that an interval of seven months or more be used will be shown by the results of other experiments referred to later in this discussion.

Additional evidence showing the influence of two other factors; namely, vaccine potency and time for producing the full immunologic effect, superimposed upon the influence of the particular kind of prior immunologic experience, is illustrated in figure 5. This summary reveals that vaccines differing in potency in fourfold and sixteenfold steps elicit different degrees of antibody response. Moreover, a second dose produces substantially more antibody in persons who have had no prior immunologic experience as compared with persons who have had a prior heterotypic experience, or in persons who have had a prior homotypic experience. After the lapse of a suitable period of time after the primary and intermediate types of response, a later inoculation will then evoke titers to levels observed for the booster-type response (fig. 5). But, it is clear that the potency of the vaccine influences the degree of response regardless of the nature of the prior immunologic experience.

So as not to complicate these matters unduly, I would like to mention that the foregoing charts have indicated that persons with no antibody to any of the three types are the ones with whom we need be concerned chiefly;

two doses of vaccine, with spacing two weeks or longer, appears to be the most efficient way to administer vaccine for the relatively limited effect that can be induced in the primary stage. Moreover, it is clear that this primary effect is influenced by the potency of the vaccine used. Figure 6 shows in somewhat more detail the influence of vaccine potency in effecting a change in antibody status in groups of individuals who had no detectable antibody prior to vaccination. It is clear that when the dose given intramuscularly is varied from 2 ml. to 0.06 ml. that there is a spread in the difference in the frequency with which antibody appears and also variation in the degree of the average response. Thus, with a potent vaccine it is possible to induce the formation of antibody in all of groups of the sizes indicated, and with weaker vaccines proportionately lesser effects are induced. The data for type 2 are illustrated in figure 7 in a somewhat different fashion, showing the geometric mean antibody level after the first and after the second dose of vaccine; in addition there is shown the percentage of individuals who had no antibody to any type before vaccination but, as a result of vaccination, developed a distinctly measurable amount of antibody; comparisons are shown after the first and second dose.

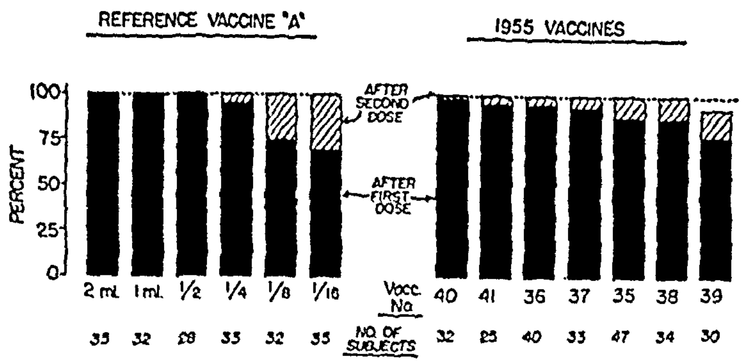

Fig. 10.—Comparison of seven lots of 1955 vaccine with reference vaccine "A." Type 2 response, showing percentage of subjects with demonstrable antibody (1:4 or more) two weeks after each of two doses given two weeks apart.

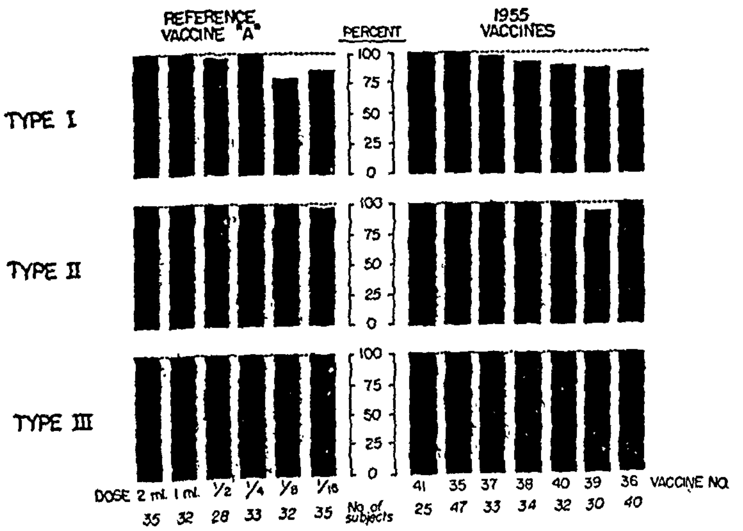

Fig. 11.—Comparison of seven lots of 1955 vaccine with reference vaccine "A," showing percentage of subjects with demonstrable antibody (1:4 or more) two weeks after two doses given two weeks apart.

The data in the foregoing figures were derived in the course of experiments designed to help establish the significance for man of a laboratory test for potency as performed in experimental animals. By varying the dose of reference vaccine "A," in studies both in man (fig. 6) and in laboratory animals (fig. 8), it then becomes possible to establish a basis for the significance of any laboratory test, whether it be done in monkeys, mice, guinea pigs, or any other animal. The underlying principle is the use of a standard reference vaccine for measuring potency in comparison with the unknown to be approved for use in man. To help further in this correlation, a group of seven batches of vaccine, prepared for use in 1955, was also tested in the same way, and the relative activity of these vaccines in children was compared with that of the different quantities of reference vaccine "A." The relative potency of the type 2 component of the commercially prepared material, expressed in terms of geometric mean titer of antibody, is shown in figure 9 and in terms of percentage of individuals who showed a response after the first and after the second dose (fig. 10). Similar data are shown in figure 11 for all three types, in comparison with different quantities of reference vaccine "A."

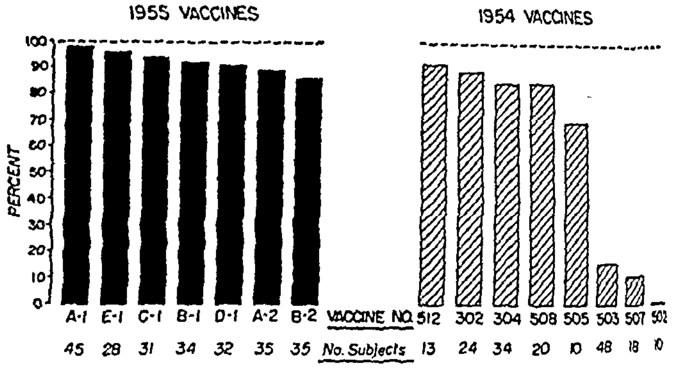

Fig. 12.—Percentage of children with no prior demonstrable antibody to any type who had a type 1 antibody response on the 14th day after first dose of vaccine.

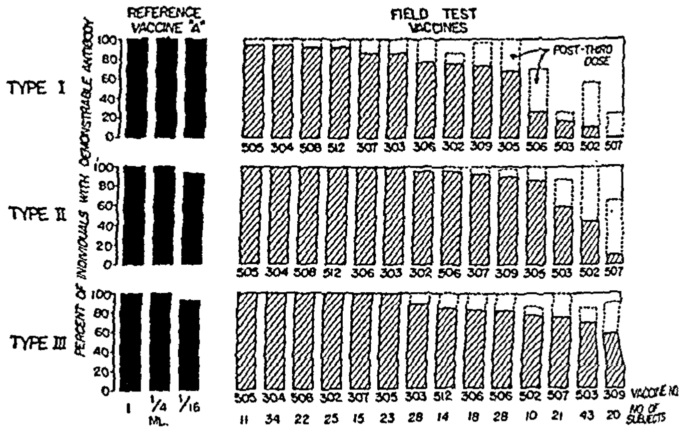

Fig. 13.—Antibody response in human subjects with no antibody for any type prior to vaccination, showing percentage of subjects with demonstrable antibody after two doses given two weeks apart (1954 field trial vaccines).

By means of such quantitative immunologic studies it is now possible, on the basis of a laboratory test performed in any of a variety of ways and in any of a number of animal systems, to predict the probable performance of any vaccine applied in human subjects so long as the vaccine in question is so constituted, and stored, that it will not deteriorate between the time of testing and the time of use. You will recall that in the vaccines prepared a year ago it has been established that the thimerosal (Merthiolate), or a decomposition product thereof, had an adverse effect upon the antigenicity, and particularly upon the type 1 component. The evidence suggests that this factor measurably influenced the response to the vaccines used in the 1954 field studies. This has been corrected by either (1) the elimination of a preservative, or (2) the use of thimerosal with edathamil (ethylenediaminetetraacetic acid), which tends to stabilize the thimerosal, or (3) the use of other preservatives. Any of the preservatives accepted for use must be shown to have no adverse effect upon the stability of the vaccine. That the vaccines used in the field trial were,[4] for the most part, less potent than those now available, is illustrated in figures 12 and 13. Figure 14 illustrates the difference in performance of vaccine with and without thimerosal, and of vaccine with thimerosal and edathamil, as compared with vaccine with no preservative.

Antibody Response to Vaccine Administered by Different Routes.—There have been a number of questions concerning antibody response to vaccine given by different routes. I would like to show, in figure 15, the data that are available on antibody response to vaccine given subcutaneously, intramuscularly, and intradermally. It is clear that 1 ml. of vaccine given intramuscularly or subcutaneously elicits about the same order of response; however, there seems always to be a slight advantage, as measured by mean antibody level, following intramuscular injection. When different quantities of vaccine given intramuscularly are compared with 0.1 ml. given intradermally, it would appear that the latter is about equal in effectiveness to 0.25 ml. given intramuscularly. Thus 0.1 ml. intradermally is not as effective, in inducing antibody formation, as is 1 ml. intramuscularly; but, it does appear that this small dose, given intradermally, is somewhat more efficient than a corresponding amount given intramuscularly.

Optimal Conditions for Eliciting the Booster Effect.—In the course of our earliest investigations, it became apparent that in man frequent multiple inoculations, given over a period of a few weeks, were an inefficient way of administering vaccine. It was apparent, furthermore, that the longer the interval between inoculations the better the effect. This total experience has indicated that 1 ml. of vaccine of reasonable potency, given to subjects who have no antidoby to any of the three types, will induce antibody formation in the majority, and a second dose, given two weeks or longer thereafter, will add to this effect; if a number of months is allowed to elapse, the advantage of the third dose will be increased as the time is prolonged, up to approximately seven months, or later, at which time it appears that the height of the hyperreactive state is reached. The evidence indicating the advantage of the relatively long interval between the second and third dose is shown in figure 16, which summarizes data from an experiment in which a sample of vaccine was used that, over the six month period of the study, was deteriorating because of the influence of thimerosal. In spite of this, the advantage of time is evident, but the full effect of the third dose that would have been elicited, had a more potent vaccine been used, is not clear from the mean antibody titers observed: Nevertheless, the trend in favor of the longer interval is evident.

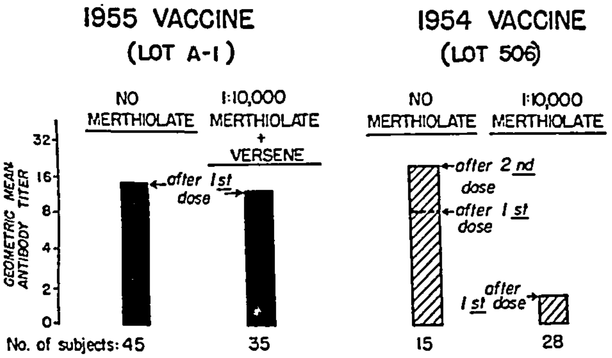

Fig. 14.—Type 1 response to 1955 vaccine (lot A-1) and 1954 vaccine (lot 506). In this instance Versene refers to edathamil (ethylenediaminetetraacetic acid).

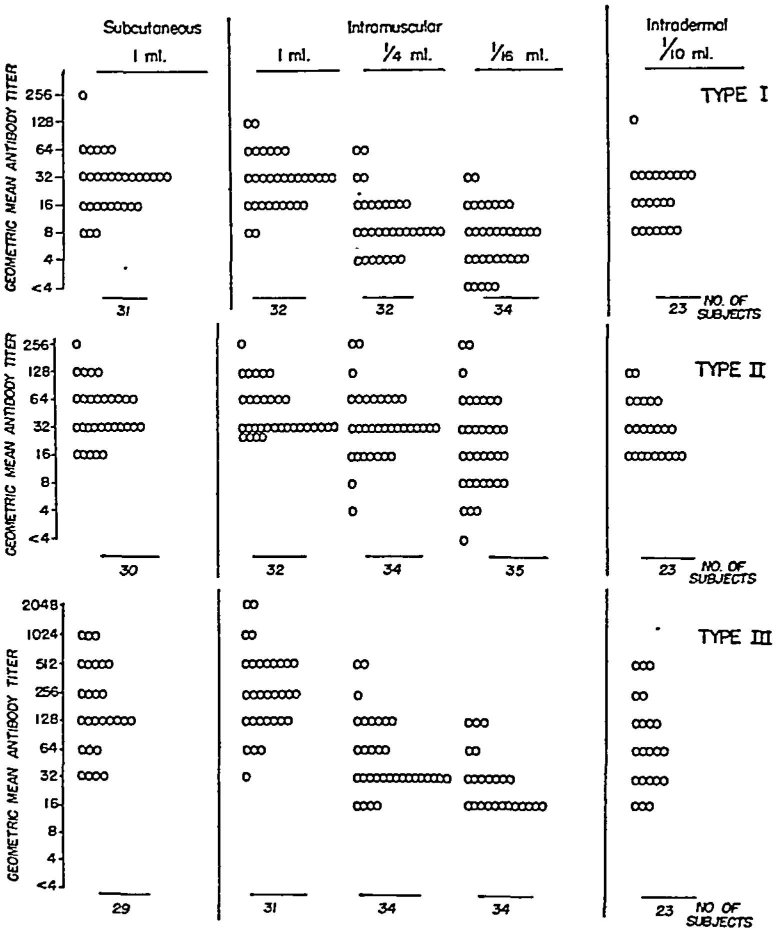

Fig. 15.—Type 1, 2, and 3 antibody response to reference vaccine "A" two weeks after two doses given two weeks apart by different routes of inoculation.

The influence of a more potent vaccine, when used for booster, superimposed upon a more adequate primary stimulus, is shown in figure 17. The degree of response during the primary phase, following the use of vaccine lots 303 and 507 is illustrated, as well as the degree of decline during the 10 months that followed; and then the degree of antibody response to the booster is also shown, along with the control representing the response of previously uninoculated children. Persons who initially had vaccine lot 303, and were then given one of the other commercial vaccines for the booster, exhibited marked rises in antibody to all three types. By comparison, individuals who had received primarily vaccine lot 507 experienced no booster effect to the type 1 component, a rather poor response to type 2, and a more adequate type 3 response. It is clearly evident that there must be a reasonably substantial primary effect for a full secondary, or booster, response. Other data bearing on the question of booster response, when the secondary stimulation is given seven months or longer after the primary, are shown in the next several figures. Here may be seen, in some instances, that even though little or no primary response was elicited, there appears to have been some sensitizing influence as evidenced by the hyperreactive response at the time of the booster.

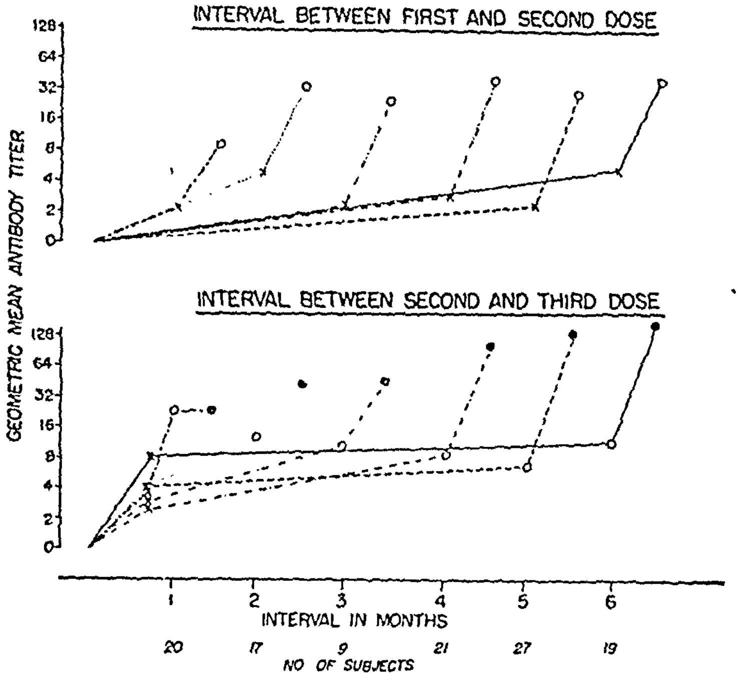

Fig. 16.—Influence of time intervals on type 2 response to second or third doses of vaccine (lot 309) in human subjects with no demonstrable preantibody to any type.

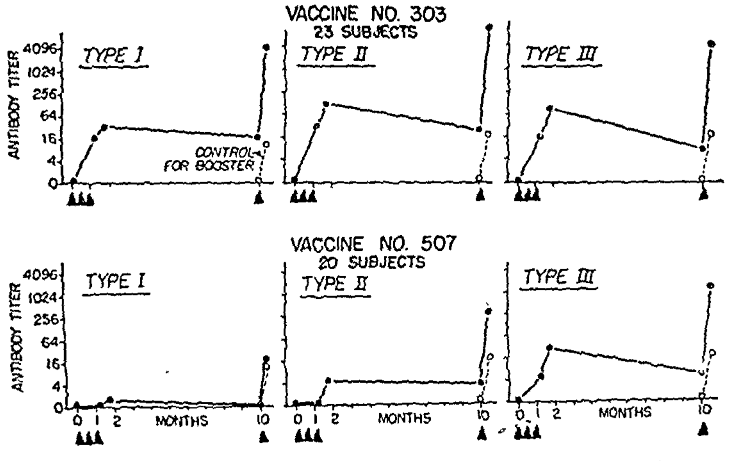

Fig. 17.—Effect of booster dose 10 months after vaccination with two different vaccine lots used in 1954 field trials.

The general pattern of response, as may be seen in these data, seems to be one in which there is a somewhat more rapid decline in the early postvaccination period followed by a more gradual decline or by a plateau, which suggests that antibody persistence following a course of vaccination of the kind here employed could be expected to persist for a number of years. Figure 18 summarizes observations in 14 individuals who, with exceptions, as noted at the different intervals, were followed for a period of one and one-half years. At that time a fourth inoculation was given to determine the character of the response that would be elicited. It is clear that the decline that occurred in the preceding year was replenished, and then exceeded to a slight degree by the second booster. These individuals will be followed to determine whether or not the rate of decline of antibody following the second booster is the same or, perhaps, more gradual than after the first. However, the magnitude of the level of antibody maintained during the year after the first booster, and the level achieved after the second is considerable, indeed. Several individual examples of persistence after primary, and of booster response, are shown in figures 19 and 20. It is to be noted that vaccine lot 503 was a relatively poor vaccine in comparison with the others used for boosters.

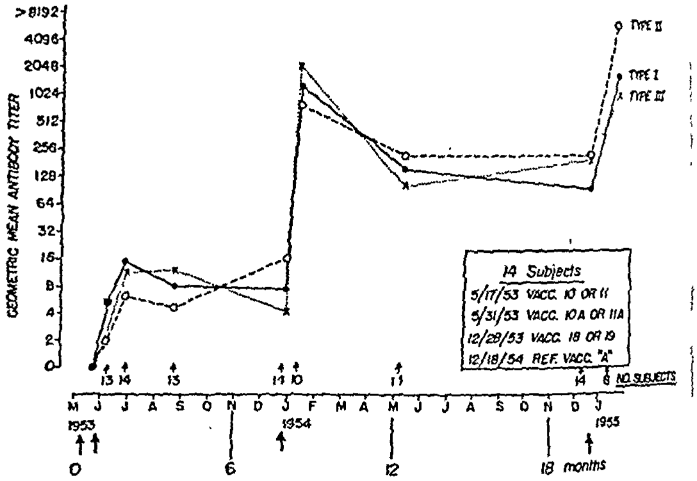

Fig. 18.—Antibody persistence after primary and secondary antigenic stimulation in children with no preantibody to any type who were observed over one and one-half years.

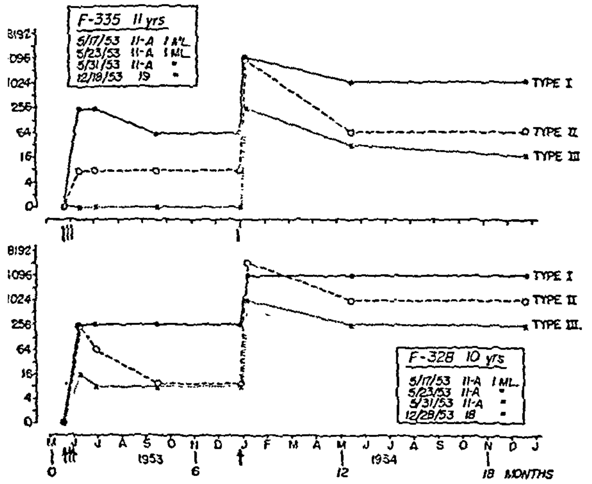
To provide further indications of trend in regard to persistence, data are presented in two individuals, of many, from whom blood samples have been tested two and one-half years after primary vaccination. These persons received 0.1 ml. intradermally of each of three virus types on two occasions, in August or September of 1952, and were then reinoculated almost two and one-half years later. The indications are that the relatively low levels of antibody, elicited by the primary immunizing procedure, tended to persist, and when a booster dose was given, even as long as two and one-half years later, a very sharp response was observed. The degree of persistence following the booster is now being followed. These examples of two and one-half year persistence are in persons who had antibody for only one type prior to first vaccination (fig. 21).

ntibody Response to Vaccination and Infection.— a matter of interest, let us compare the levels of body observed in vaccinated individuals with those erved in persons who have experienced natural in- ion. To illustrate this point, figure 22 shows the pre- cination and postvaccination antibody titers of a up of 61 individuals, for whom we had such data, n among those who had received their initial inocula- s with vaccines lot 303, 305, 306, or 512. In the booster period, the type 1 antibody levels of all in- iduals were below 1:32; 14 days after the booster y all had levels beyond this range, with a high pro- tion clustering at the level of 1:8,000+. For com- ison, there is charted the levels of antibody observed group of 56 persons with type 1 paralytic polio- elitis, and from whom serial bleedings were obtained pproximately weekly intervals while they were hos- ilized. The geometric mean level of antibody was 28 at the time of hospital admission and shortly r onset of paralysis; there was no serologic evidence prior infection with any other virus type. The anti- dy measurement recorded in this figure was the high- observed in the series for each individual; the geo- tric mean level of the highest titers was slightly less n 1:1024. From other experiences, it is to be ex- cted that these high titers will decline over a period of e and will stabilize at a mean level of approximately 128.



ig. 19.—Antibody persistence after primary and secondary antigenic ulation in two children with no preantibody to any type.

It is evident from these data that there occurred, as a ult of an infection with paralytic consequences, levels antibody that in general were higher than that induced primary vaccination with a killed-virus vaccine. How- r, it was equally clear that the level of antibody in- ced with a killed-virus vaccine, when a booster dose s given at a suitable interval, was higher than that luced by the infectious process.

In the right-hand portion of figure 22 are data from other group that is of interest. These data are from study of 27 children who had been vaccinated either in the spring of 1953 or the spring of 1954, and, in the course of follow-up bleedings, in the winter of 1953 or 1954, respectively, it was evident that these children had experienced a natural infection. This was indicated by the sharp difference in the level of antibody for one type only, when the early and late postvaccination blood samples were compared. In this group of 27 are 2 children who had a type 3 infection, diagnosed serologically; 12 had type 1 infections; 13 had type 2 infections. It is clear that the level of antibody observed in these subjects was, in general, higher than that observed in paralyzed convalescents. It is as if infection, in a previously vaccinated person, elicits a booster-type antibody response corresponding to the infecting type.

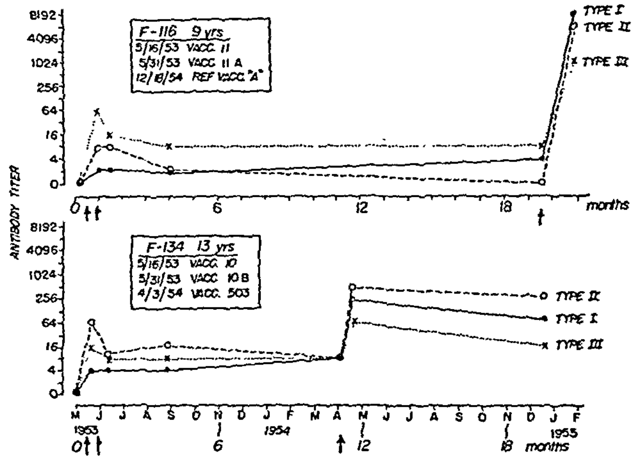


Fig. 20.—Antibody persistence after primary and secondary antigenic stimulation in two children with no preantibody to any type. who were observed over one and one-half years.

There is a similarity between the levels of antibody following a booster injection, and the postinfection levels in previously vaccinated individuals. The distribution of levels in each appear to be higher than that observed in recently paralyzed convalescents. It would seem from these data, therefore, that the assertion that the levels of antibody following the use of a killed-virus vaccine are lower than those observed in persons who have been infected is, indeed, true. But this is only part of the truth.

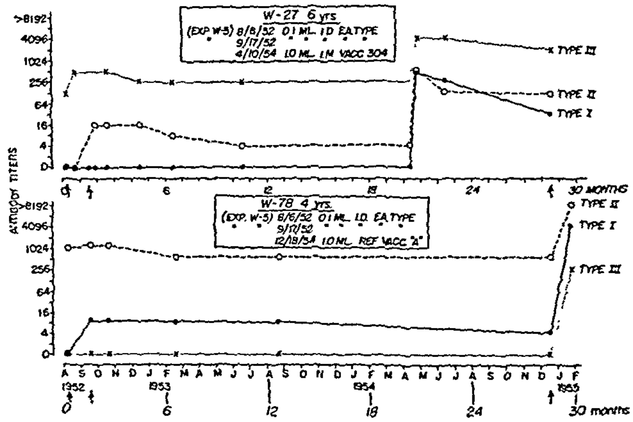

Fig. 21.—Observations over two and one-half years in two children of first group inoculated.

The whole truth indicates that the level of antibody induced by a properly prepared killed-virus vaccine, properly used, can be higher than that level induced by infection.

COMMENT

It should be clear from all that has been presented that the objective of the immunization process is to effect an immunologic response that will last for a considerable period of time. It appears that this can be accomplished by the introduction of an adequate antigenic mass, the influence of which will be evident after each of the three inoculations. The height of the antibody titer induced by the primary vaccinating doses (two doses spaced two to four weeks apart) is influenced by the intensity of the primary stimulus; i. e., dosage and potency of the vaccine. The height of the antibody titer after the booster dose is influenced by the length of the interval between the primary and secondary injections and by the size and potency of the booster dose. The level of antibody present at any given time after vaccination varies among individuals but is influenced by the total prior immunologic experience as well as by the interval that has elapsed after vaccination. The rate of decline from the different levels achieved after primary and booster doses has been described and in general appears to be more rapid shortly after the postinoculation level; this is followed by a plateau or a very gradual decline. In addition to these effects that are measurable directly, there appears to persist a state of heightened immunologic reactivity that is evident upon reinoculation or upon exposure. This state of hyperreactivity probably does not decline with time. Because of it, antibody levels may be further enhanced by revaccination, if need be, or will be augmented in the course of natural exposure.

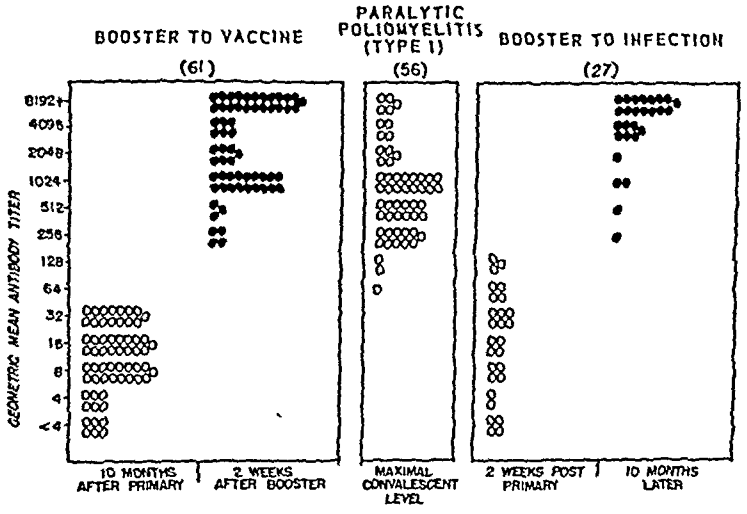

Fig. 22.—Comparison of antibody response to vaccination and to infection.

Although we have said that the ultimate objective of these investigations is to provide the basis for the preparation and the use of a safe and effective vaccine against paralytic poliomyelitis, the orientation of our studies at this time is to determine the degree of completeness with which effectiveness can be demonstrated—first, by means of blood tests, and, ultimately, by performance in the field. Thereafter, both by blood tests and by field experience, it will be possible to determine whether further inoculations beyond the course now recommended will be required—and if so, when. As for the resolution of the problem of vaccine safety, this is linked to an understanding of the dynamics of the virus inactivation reaction and the application of this knowledge. As for the resolution of the problem of effectiveness, this will come from an understanding of the dynamics of the immune process, upon the basis of which recommendations may be made; physicians and health officers can then apply vaccination to elicit its full potential effectiveness both in the individual patient and in the community as a whole.

The Mutation of Viruses.—In 1918 and 1919 influenza, known for centuries as a distressing but seldom fatal disease, suddenly turned virulent and swept across the world in the greatest epidemic of modern times. Then, just as suddenly, the fatal form of influenza disappeared, leaving some 25 million dead. Where had this scourge come from and where had it gone? At the time there was no accepted answer. We now know that influenza is a virus disease, and we believe that the 1918-1919 pandemic was simply a catastrophic example of biological mutation. . . . What chemical events occur when a virus mutates? . . . All known viruses have two chemical constituents: protein and nucleic acid. Like other proteins, virus proteins are very large molecules composed of much smaller units, the amino acids. The protein can easily be broken down into these units, and it is found that there are only some 20 different amino acids in even the most complex protein. Nucleic acids, found in all living cells, are also huge molecules. They can similarly be broken down into a few simple components; inorganic phosphate, two sugars and five organic bases. To the best of our present knowledge, these simple constituents of proteins and nucleic acids (with a few exceptional derivatives and close relatives) are the building blocks both of all viruses and of the chromosomes of all living things. . . . If the biological properties of a virus differ from those of its parent, is this difference reflected in the make-up of its protein? This question was investigated with the famous virus that causes the mosaic disease of the tobacco plant. . . . One of the most interesting results came out of the comparison of the original tobacco mosaic strain and a "killer" strain called J14D1. Young Turkish tobacco plants infected with the original strain suffer a characteristic mottling of the leaves accompanied by a certain amount of blistering, distortion and stunting. However, the plants continue to grow, reach maturity, flower and bear viable seed. Identical young plants infected with J14D1 are rapidly killed. Yet the killer strain differed from the original one only in its proportion of two amino acids: glutamic acid and lysine. Even in this proportion it differed from the original strain only by 10 to 20 per cent. In all other respects the two strains seem identical. This is a striking illustration of how small the chemical difference between a mild strain of virus and a killer may be.—C. A. Knight and D. Fraser, The Mutation of Viruses, *Scientific American,* July, 1955.

PUBLIC HEALTH IMPLICATIONS IN A PROGRAM OF VACCINATION AGAINST POLIOMYELITIS

Leonard A. Scheele, M.D., Washington, D. C.
and
James A. Shannon, M.D., Bethesda, Md.

In public health and preventive medicine, the application of a new prophylactic agent, whether to large population groups or to an individual patient, requires careful consideration of many factors. The safety, potency, and efficacy of the agent are primary considerations. To these must be added problems of dosage, methods of administration, and the possibility of undesirable reactions in patients. In the case of large-scale immunization programs, account must also be taken of the cost and availability of the agent and the organization of personnel and facilities. These many technical, medical, and administrative problems must be weighed against the seriousness of the disease and the vulnerability of particular population groups. The use of the Salk vaccine against paralytic poliomyelitis has presented all of these general problems and some specific problems that were unanticipated by many individuals and groups working with the program. Our purpose is to present a brief report on some of these problems and the measures adopted for their solution.

PROBLEMS OF QUALITY CONTROL

The Biologics Control Law of the United States was first enacted in 1902. With minor changes, it was reenacted as Section 351 of the Public Health Service Act of 1944. Under this law, manufacturers are licensed by the Secretary of Health, Education, and Welfare, to produce specific biological products for interstate sale and for export. Licenses are issued by the Secretary upon recommendation by the Surgeon General of the Public Health Service. The minimum requirements to assure the safety, purity, and potency of each product are issued by the Public Health Service. The regulations governing biologics control are promulgated under the law by the surgeon generals of the Public Health Service, the Army, and the Navy, with the approval of the Secretary. Since 1902, the Public Health Service has maintained a biologics control unit staffed with competent scientists and devoted exclusively to the research, testing, inspectional, and administrative aspects of this statutory function. The legal responsibilities of the Public Health Service for promulgating standards for the quality control of biological products sold in interstate commerce have governed the official position that our organization has occupied in the 1955 poliomyelitis vaccination program.

Until April 12, 1955, however, poliomyelitis vaccine was an unlicensed, experimental product. The vaccine used in the field trials of 1954 was produced by commercial manufacturers under contract with the National Foundation for Infantile Paralysis, in accordance with specifications furnished by that organization. These specifications were drafted between December, 1953, and February, 1954, on the basis of information from numerous sources and were adopted by the National Foundation's vaccine advisory committee. Dr. Salk provided information about his own laboratory experience in the development and experimental testing of the prototype vaccine. The Connaught Medical Research Laboratories of the University of Toronto, Toronto, Canada, shared its experience in the growing of virus in large quantities by tissue culture methods. At the request of the Foundation, Dr. William Workman, Chief of the Laboratory of Biologics Control of the Public Health Service, and Dr. Joseph Smadel of the Army Medical Services Graduate School provided their expert knowledge of biologics manufacturing to aid in developing the specifications. The vaccine advisory committee expressed its confidence in the safety of the proposed product under the conditions prescribed in its specifications. Trivalent-pool material from each lot of vaccine used in 1954 was tested by the manufacturer, by Dr. Salk, and by the Laboratory of Biologics Control prior to final filling of the containers.

Production and testing in the first few months of preparation for the field trials were fraught with difficulties. Live virus was found in some preliminary lots that were rejected. The results of tests on specific lots varied in the three testing laboratories. However, by the time the vaccine advisory committee decided to go ahead with the field trial, two manufacturers had produced a series of lots consistently reported negative by all three laboratories. More stringent tissue culture tests had been incorporated in the requirements. Dr. Salk also had vaccinated 7,507 children with vaccine prepared by the manufacturers, with no harmful effects. This test was regarded as a good preliminary check on the safety of commercially produced vaccine. The Laboratory of Biologics Control had participated in all these developments. In recognition that manufacturers would apply for licenses to produce the vaccine, if the field trials were successful, the Laboratory, on May 20, 1954, issued tentative "Minimum Requirements, Poliomyelitis Vaccine." Vaccine manufactured prior to April 12, 1955, was prepared to meet these provisional standards.

Licensing and Production.—Immediately after the now-historic presentation of Dr. Francis' report on the 1954 field trial, a group of scientists met with the Chief of the Laboratory of Biologics Control at Ann Arbor, Mich., to advise on the licensing of production of the vaccine. The advisory group unanimously recommended licensing, and Dr. Workman transmitted his favorable

Surgeon General, U. S. Public Health Service, Department of Health, Education, and Welfare (Dr. Scheele), and Associate Director, National Institutes of Health, U. S. Public Health Service, Department of Health, Education, and Welfare (Dr. Shannon).

Read in the Panel Discussion on Prospects for the Control of Poliomyelitis before the Joint Meeting of the Section on Pediatrics and the Section on Preventive and Industrial Medicine and Public Health at the 104th Annual Meeting of the ican Medical iation, Atlantic City, June 7, 1955.

recommendation to the Surgeon General in Washington, D. C., who in turn recommended that the Secretary of Health, Education, and Welfare issue product licenses to the six firms whose applications were pending. These were the Cutter Laboratories; Eli Lilly & Company; Parke, Davis & Company; Pitman-Moore Company; Sharp & Dohme; and Wyeth Laboratories, Inc. The decision to license was based on the following factors. Each of the manufacturers is an established and reputable firm with which the Laboratory of Biologics Control has dealt for many years. Each held a general license to manufacture biological products. Each held licenses to produce numerous specific products. Each plant had been inspected during the period from September, 1954, through January, 1955, and the facilities for manufacturing and testing poliomyelitis vaccine had been found acceptable. The competence of the scientists in charge of production in each plant was known and respected. All but one firm (Sharp & Dohme) had had experience producing the vaccine in 1954. The manufacturers were considered to have overcome the earlier difficulties in obtaining a safe commercially produced vaccine. The Laboratory of Biologics Control had done complete tissue culture and monkey tests on six lots from five manufacturers (excluding Lilly) and numerous tissue culture tests on other lots from all manufacturers. The final factor in the decision to license was the evidence of safety and efficacy presented by Dr. Francis' evaluation of the field trials.

Thus, the national program of poliomyelitis vaccine release began on April 12. Stocks of vaccine were on hand, tested by the manufacturers in anticipation of licensing. Some lots had been completely tested at the National Institutes of Health, but tests on other lots had not been completed. Lots that had passed safety tests in the manufacturers' laboratories were released. No lot was released whose protocol did not show a clear record of performance in the manufacturer's tests. The situation with respect to poliomyelitis vaccine was unique. In contrast with the very slow, gradual development of other prophylactic agents, a great deal of experience in the use of this vaccine had been accumulated in the space of two years. The full record of events in the manufacture and testing of each lot (a protocol) had been successfully used for many years to evaluate the manufacturer's compliance with regulations or standards established for numerous biological products. The staff of the Laboratory of Biologics Control concluded that release on protocol review would be sufficient on this product.

In addition to Dr. Salk's trials with vaccine produced in his laboratory, covering approximately 14,000 individuals, more than 400,000 children had received commercially produced vaccine in 1954. The evidence from the field trial evaluation was interpreted to indicate the safety of commercial products, as prepared for that experiment. It was also believed that the manufacturers, armed with additional experience in production and with testing standards then thought to be adequate, would be able to prepare vaccine with a satisfactory margin of safety. The favorable experience with tests of numerous lots from all manufacturers was interpreted to support confidence in the process, the testing requirements, and the manufacturers' ability to apply them. During the last week of April, 1955, when cases of paralytic poliomyelitis were reported in children vaccinated with materials produced by the Cutter Laboratories, the Public Health Service immediately requested the withdrawal of all lots of that manufacturer's product that had been released previously. Simultaneously, a thorough investigation of the plant was instituted, and extensive laboratory tests of the material were begun. Studies of the production and testing of poliomyelitis vaccine in the hands of the other licensed manufacturers were also undertaken. The purpose of these studies was to review the total experience of the manufacturers in the production and testing of poliomyelitis vaccine, in order to determine whether there were common problems related to the basic method of production and the the adequacy of testing requirements. It was believed that should such common problems exist, steps could be taken to improve the methods of production and increase the adequacy of testing before additional lots of vaccine were released. The production records of all lots of vaccine that any firm had produced for the 1955 program, whether submitted for release or not, were studied. We then learned that such common problems had, in fact, existed. The producers had had difficulties in processing and testing some lots. If lots were clearly unsatisfactory, the manufacturers did not offer them for clearance, and therefore the protocols were not submitted and studied. The difficulties experienced by the manufacturers, as well as their successes, were now seen to provide valuable information that led the Public Health Service to require more adequate safety testing. The biologics control procedures in use prior to, and immediately after, April 12 had failed to provide adequate review of this total experience, with its inconsistencies in the behavior of a new and complex product, now being dealt with in large-scale production. In Cutter Laboratories' case, the health service is comparing that manufacturer's experience with the data recently accumulated from other producers, in an attempt to determine the extent to which the Cutter operation involved problems common with those of other manufacturers and the extent to which unique problems might account for the probable presence of active virus in a few lots of the Cutter material.

Decisions and Actions.—Outstanding virologists and epidemiologists from several private and public institutions have assisted in this review of manufacturing and testing procedures. Both technical and management representatives of all six licensed firms have cooperated fully in providing full information on their experiences. In brief, the information and advice derived from these studies and consultations during the past six weeks, have led to the following decisions and actions on the part of the Public Health Service: (1) request that the Cutter Laboratories withdraw all its supplies of poliomyelitis vaccine and initiation of thorough investigation, April 27; (2) activation of a Poliomyelitis Surveillance Unit in the Communicable Disease Center (PHS) to conduct epidemiological studies of poliomyelitis cases in vaccinated individuals, April 28; (3) initiation of additional laboratory studies of the vaccine from all manufacturers and halt in release of additional lots, April 30; (4) recommendation that the vaccination programs be halted until further information could be obtained on quality of vaccine, May 7 (based on presentation by manu- turer's technical representatives of new data on pro- ction problems); (5) inspections of plants of five li- sed manufacturers, May 9-20, with subsequent clear- ce of some lots previously released and of additional s awaiting release; (6) establishment (May 26) of a manent Technical Committee on Poliomyelitis Vac- e to review lots of vaccine, to recommend action on m under the revised standards, and to guide future de- opment of the vaccine program, seeking further im- ovements and refinements both in production and test- ; and (7) revision of the minimum requirements for oduction and testing with announcement of the ended standards, May 26.

SCIENTIFIC BASES OF REVISED MINIMUM REQUIREMENTS

The body of new information acquired in the past six eks is the basis of changes both in manufacturing pro- lures and testing. Although these changes have pro- ced a dearth of vaccine at present, they will make pos- le a safer vaccine when the product begins to flow ain in channels of distribution. Dr. Salk has presented some detail the background of information upon ich his contributions rest. What we shall present re- es primarily to the problem of safety and originates in demonstration that safety and effectiveness are not ompatible.

Strain Selection.—The selection of the Mahoney ain for the type 1 component of the vaccine requires ecial comment. This strain is characterized by great ulence because of its capacity to multiply rapidly in traneural tissues. Because of this characteristic, it is at ist theoretically possible for a minute dose of living us to produce incapacitating paralysis. The hazard of Mahoney strain has led some virologists to criticize inclusion in the Salk vaccine, despite its ability to in- ce a high titer of type 1 antibody. This objection has l those responsible for vaccine development in Den- irk to exclude it in their routine vaccine production is spring. They have used the Brunhilde strain and ve compensated in part for its poorer antigenic proper- s by including proportionately more type 1 antigen an types 2 and 3 in the final vaccine.

Inactivation.—An important feature of Dr. Salk's nception of the preparation of a suitable vaccine lies the principle that presumes a large margin of safety the inactivation process itself.[1] This point warrants iscussion. Figure 1 shows the theoretical course of an iactivation process as envisaged by Dr. Salk. It starts ith the concentration of tissue culture infective doses one million per milliliter, a common concentration. uring the initial phase of the inactivation process, the g of the virus concentration falls linearly with time, id 48 to 72 hours later reaches zero. At this time, the ation of live virus is 1.0 tissue culture infective illiliter of viral suspension. Figure 1 has been the intercept time of the inactivation at three days. By extrapolation, the ssumed to be reduced to 1.0 tissue cul- it per one million milliliters at six days, culture infective unit per 1.0×10^{-12} ml. at nine days. This concentration is of such a low order that its significance can be grasped only when the numbers are reduced to common terms. The prediction means that if the reaction proceeds as indicated in figure 1, there will be a concentration of living virus in the order of 1 tissue culture infective unit in each million tons of inactive viral suspension, at the end of nine days. During the production of field trial vaccine, when the initial part of the reaction was shown to proceed according to the original concept, the single strain pool was considered suitable for pooling without further examination for live virus.

There are alternatives to this theoretical conception. The viral suspension is not a monophasic system but consists of a number of discrete particles in suspension. At high concentrations, these may behave in a manner not dissimilar to a monophasic system, and during the first period of inactivation process the system may yield data that are describable by a simple equation derived from the law of mass action. However, with the progression of the reaction and at lower live particle concentrations, the heterogeneity of the system should assert itself. The course of the reaction under this circumstance may depart from that of a simple first-order reaction, as derived from the law of mass action or from concepts of surface chemistry of a simple system. In high dilution, the residual live virus will probably consist of particulates of varying size and shape and in varying degrees of aggregation. Particulates contained in such a mixture cannot be expected to inactivate at the rate calculated from the behavior of the reaction during its initial phase. During this phase, the reaction will be dominated by that portion of the particulate mass that is more easily inactivated. This would appear to be the bulk of the material undergoing inactivation. The extent to which the inactivation process departs from a straight line, even in the initial phase, will be a reflection of the extent to which the particulate mass is composed of particulates

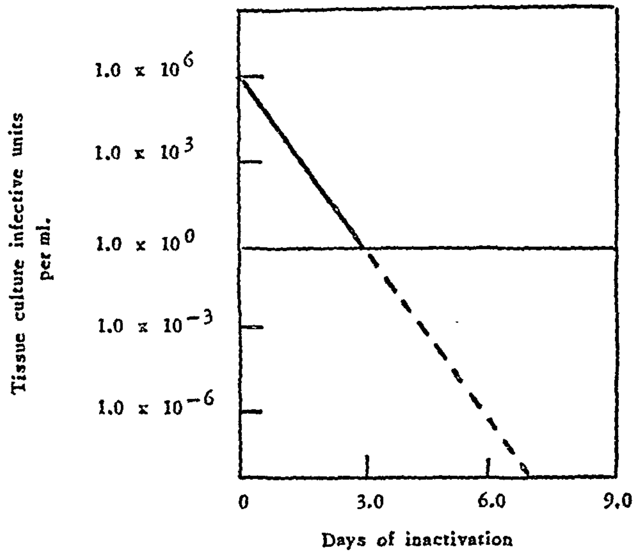

Fig. 1.—Theoretical curve of inactivation of poliomyelitis virus (after Salk).

---

[1] Salk, J. E., and others: Formaldehyde Treatment and Safety Testing of Experimental Poliomyelitis Vaccines, Am. J. Pub. Health 44:563-570 (May) 1954.

of differing sensitivity (an index of heterogeneity) and the extent to which there are other physical and chemical variations in different proportions of the total suspension (problems of mixing).

These considerations have a practical bearing on manufacturing problems. Heterogeneity in the system can operate to remove the so-called built-in factor of safety. This consequence is demonstrated graphically in figure 2. The system is obviously more complex than is given in this example, which merely points up the importance of a minute portion of the initial virus mass in conditioning the later stages of the reaction. Additional formal treatment is not warranted. In figure 2, curve *A* describes the reaction proceeding in the original conception (fig. 1) when the concentration of live virus at the beginning of the reaction is one million per milliliter (1.0×10^6). Curve *B*, in which the initial live virus concentration is taken to be 1,000 particles per milliliter, shows a similar reaction proceeding at a rate one-half as fast as in curve *A*. In curve *C*, the rate is one-fourth of *A* and the initial live virus concentration is taken at 13 particles per milliliter. The composite inactivation curve of a mixture of the three is shown as curve *D*. Starting with a suspension composed of the three types of particles in the assumed concentrations, the summation of the three reactions will be dominated by reaction rate of curve *A* initially and of curve *C* at a later time. Hence, we may conclude that observations during the initial phase of the reaction do not constitute an adequate basis for judgment of the course of the remainder of the reaction in these circumstances.

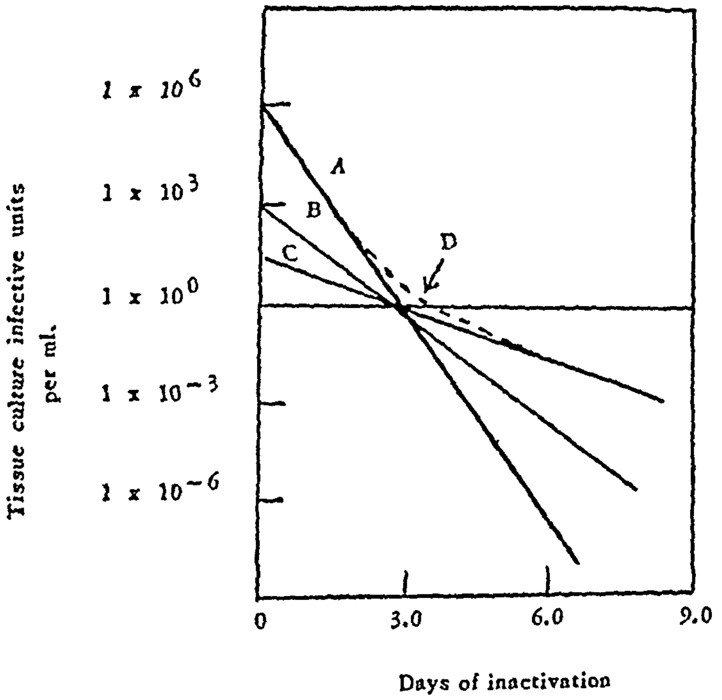

Fig. 2.—*Inactivation of poliomyelitis virus. A, reaction when concentration of live virus at the beginning is one million per milliliter. B, initial live virus concentration is 1,000 per milliliter. C, initial live virus concentration is 32 per milliliter. D, composite inactivation curve of a mixture of the three.*

Another factor argues against acceptance of the original concept as a basis for an interrelated combination of inactivation and safety. The suspending solution contains protein coagulable by formaldehyde, which favors the formation of viral particulates occluded in minute protein precipitates not generally distinguishable to the eye. Such particulates would be relatively inaccessible to the inactivating formaldehyde. The extent to which a combination of the foregoing factors influences the course of inactivation will also be reflected in the extent to which the actual curve of inactivation departs from a straight line.

SAFETY TESTING

A safety test, generally speaking, is a laboratory procedure utilized as a part of quality control to separate that which is unsuitable from that which is suitable. Safety tests for the Salk poliomyelitis vaccine were devised mainly to find contamination and process failures from accidents in manufacture and not to detect small amounts of residual live virus that the process was believed to have reduced to an immeasurably low, harmless level. The primary safety data were conceived as being those that described the initial stages of the inactivation process. The prime factor of safety, according to the original conception, was built into the process of inactivation. However, insofar as the process departs from that theoretical conception, whether because of deficiency in the conception or because of inadequacies in the handling of the process, the safety testing becomes of increasing importance both as a guide to processing and as a final determinant for safety. The two tests for the presence or absence of live virus utilized in the quality control of the vaccine are the monkey test and the tissue culture test, in routine manufacture.

Monkey Test.—The monkey test is very crude, as was demonstrated in the spring of 1954, incidental to the preparation of material for the field trial. This will not be discussed, except to point out that the inability of this test to discriminate between vaccines containing low concentrations of live virus demonstrable by tissue culture and those containing none, has been the common experience of each of the manufacturers. Their data show repeatedly that live virus detectable by tissue culture is not detected by the monkey test as presently performed. Consideration should be given to increasing the sensitivity of the monkey test by concentration of the test material. Otherwise the test should be discarded.

Tissue Culture Safety Test.—Certain assumptions have been made as a basis for analysis of the sensitivity and reliability of the tissue culture safety tests. In general, these assumptions provide an estimate of greater reliability than actually obtains. A somewhat comparable analysis with respect to vaccine for foot-and-mouth disease has been made by Henderson,[2] and include the following assumptions. 1. Residual live virus can be defined in terms of the number of discrete particulates, varying from zero to some finite number, contained in a unit volume (1.0 liter) of antigen suspension. 2. Random distribution (truly effective mixing) of these particulates obtains. 3. One particulate is an effective dose for a sensitive tissue culture preparation. More than one particulate is required for an insensitive tissue culture preparation or for an infection in a series of relatively nonsensitive tissue culture preparations. 4. The total volume of virus suspension is no less than 10 liters.

---

[2] Henderson, W. M.: Significance of Tests for Non-Infectivity of Foot-and-Mouth Disease Vaccines, J. Hyg. **50**:195-208 (June) 1952.

Certain statistical probabilities have been calculated, using the Poisson distribution, which is applicable in this case. Table 1 shows the probability of failing to demonstrate live virus at different concentrations when different size samples are tested. Table 2 shows the chances of picking up a positive lot, when the upper level of acceptable viral concentration is set at 5 infective units per liter and with the sample volumes commonly used by each of the manufacturers of the vaccine. One milliliter was tested in tissue culture for each liter of single-strain and polyvalent pool. It is quite apparent that different standards of acceptability as regards the possible presence of infective particles have been incorporated into the processes of the different manufacturers. This variation stems from the erroneous assumption inherent in the "Minimum Requirements of April 12, 1955" that the volumes used in the tests should be directly proportional to the total volume tested. Routine testing on such assumptions would not provide a reasonable assurance of the absence of live virus in the finished vaccine of certain of the manufacturers. It is important to note, however, that the volume of material tested in clearing vaccine for the field trial in 1954 would place an even lower value of confidence in this material. A more rational basis for safety testing has been adopted. The objective has been to design a testing procedure that will identify lots of vaccine containing more than a given concentration of live virus particulates. Such a procedure does not bear upon the level of viral concentration that will be infective to man. (Actually the determination of the infective level for man is today beyond the possibility of direct examination.)

TABLE 1.—*Size of Sample Needed to Keep Probability of Getting Negative Test Result Below Specified Level at Certain Postulated Concentrations of Particulates Containing Live Virus and at Two Levels of Test Sensitivity in Lots of Ten Liters or More*

MANUFACTURING EXPERIENCE

The systematic survey conducted in each of the plants producing poliomyelitis vaccine has been mentioned. Some of the results of this survey are presented here. The process of inactivation of the poliomyelitis vaccine when done on a large scale does not seem to follow the original concept in the hands of any manufacturer with any degree of reliability, as shown in part by a curvilinear, rather than a straight-line, relation between time and the log of the residual live virus in the initial phases of the reaction. It is also evidenced by the frequent occurrence of a positive tissue culture test from 9 to 12 days after the beginning of the inactivation process. It is also apparent that the inactivation process has not yielded consistent results in the hands of most of these manufacturers. That is to say, the initial test performed at the time when all live virus was presumed to have been inactivated shows that an appreciable proportion of single-strain pools still contained live virus (table 3). This is an important finding. It demonstrates that the departure of the process from the theoretical conception greatly diminishes the factor of safety that was believed to have been built into the basic process. Consequently, principal reliance for the exclusion of live virus must be placed upon the safety test in the final vaccine.

TABLE 2.—*Size of Sample Used in Safety Testing, by Tissue Culture, Prior to May 22, 1955*

	Size of Sample, Ml.		
Laboratory	Single Strain Pool	Polyvalent Pool	Chances of Picking Up Positive Lot,* %
A	60	150-175	70
B	500	360	99
C	400-500	1,200-1,600	Over 99.9
D	25	300	80
E	40-45	140	60-70

* Assuming lot had five tissue culture infectious doses per liter and assuming high sensitivity for all tissue cultures.

The data on the safety tests performed immediately after combination into trivalent pools offer further evidence of inadequacy (table 4). Live virus was frequently found in a trivalent pool when this had been presumed to be free of live virus on the basis of testing applied to the monovalent pools that composed it. In the hands of certain manufacturers (for example, laboratory C), when the trivalent pools were formed prior to the completion of the safety tests of the single-strain pools, it was impossible to predict the outcome of the tests (table 5). One can only conclude from such data that the tissue culture test for active virus, as applied to the single-strain pool, was not an adequate process guide, nor did it provide a sense of security that sizeable concentrations of live virus would not be included in the trivalent pool. This again emphasized the inadequacy of the safety tests as performed during the period of processing and placed an even greater burden on the final safety testing of the trivalent pool just prior to subdivision and packaging.

TABLE 3.—*Positive Single Strain Pools on Initial Test*

	Lots	
Laboratory	No.	% Positive
All	809	11
A	97	21
B	234	19
C	85	8
D	267	5
E	126	2

Detailed tables show an almost random distribution of positives in relation to processing data. Positive tests occurred in a sufficiently high proportion of instances to minimize the reliability of a single subsequent negative test, whether used for process control or as a final test of safety (table 6). These data summarize the experience of laboratory B in reprocessing single-strain pools after a positive tissue culture test. Of a total of 234 single-strain lots tested, 44 were positive on the original test. These were reheated at 37 C for an additional two to three days, after which negative tests were obtained from 21 lots. Some of the remaining lots were then subjected to a second inactivation period, resulting in negative tests for nine. Two continued to show positive tests; a third continued to be positive after three inactivation periods. The remaining 11 pools were otherwise disposed of and do not bear on the problem of inactivation.

TABLE 4.—*Positive Trivalent Pools on Initial Tests*

Laboratory	Lots No.	 % Positive
All	127	13
A	21	33
B	31	9
C	22	23
D	8	..
E	42	4

That repeat testing favors the occurrence of negative tests by chance, even if reinactivation is ineffective, is indicated by the data in table 7. Here, 32 polyvalent pools are examined in relation to their history. Twenty-three were negative in the initial test of their single-strain ools, as well as in the trivalent pools. The remaining e polyvalent pools contained at least one positive gle-strain pool that had been combined into a trivalent pool after reinactivation. Three of these nine showed a positive tissue culture safety test in the trivalent pool.

In summary, the plant data show departures from the theoretical data, as well as a lack of discrimination in the previous safety testing practices. There are exceptions to certain of these criticisms, but these need not be discussed here, since the examination of the data has been aimed primarily at finding weaknesses in the process, some of which were found in each laboratory.

TABLE 5.—*Relation of Tissue Culture Results in Single Strain Pools and Polyvalent Pools When Tests Are Done Independently*—Laboratory C*

		Polyvalent Pools Negative	 Positive	 Total
Single Strain Pools	Negative	12	3	15
	Positive	5	2	7
	Total	17	5	22

* Single strain pools were combined into polyvalent pools before results of tissue culture tests on individual pools were known. The tests are, therefore, independent, offering an experiment of opportunity on the chance nature of results apparently obtained. Of 10 lots with positive results obtained by tissue culture in either single strain pools or in the polyvalent pools, only 2 showed positive results both before and after pooling.

FORMULATION OF NEW STANDARDS

As a result of the foregoing considerations, it has been possible to develop definitive modifications of the safety requirements controlling the manufacture of poliomyelitis vaccine. 1. Single-strain pools are to be inactivated in 1:4,000 formaldehyde at 37 C, for such a period of time as will permit the obtaining of two consecutive negative tissue culture tests separated by a three-day interval prior to the termination of inactivation. In order to assure the exclusion of live virus particulates above a minimal concentration, the volume of single-strain pool material used for each safety test must not be less than 500 ml. In application, this means a negative tissue culture test on the sixth to ninth day from the beginning of inactivation and a second negative tissue culture test three days thereafter. Observations during the early part of the inactivation process can be limited to the demonstration that the process is proceeding as usual, and no dependence need be placed on the precise rate of initial fall in the concentration of live virus. 2. Once having obtained a positive tissue culture test after the initial inactivation period, only one additional inactivation period is permitted. During this retreatment, two negative tissue culture tests must be obtained on a volume of not less than 500 ml. each, separated by three days. 3. The trivalent pool is to be considered suitable for vaccine manufacture if a negative tissue culture test is obtained, utilizing 1,500 ml. of the pool in the tissue culture test. 4. Industrial practices relative to stirring for purposes of processing and sampling, as well as to temperature and pH control, must be such as to produce consistent inactivation. 5. Finally, breaks in manufacturing routine are excluded through a test for live virus in final contai material.

TABLE 6.—*Reinactivation History of a Number of Single Strain Pools—Laboratory B*

Single Strain Lots Tested	No.
Total	234
Negative on original test	190
Positive on original test	44
Reinactivated once with negative test	21
Reinactivated, positive test; second reinactivation with negative test	9
Reinactivated, positive test; second reinactivation with positive test; rejected	2
Three reinactivations, each followed by positive test	1
Reinactivation started, but test incomplete	7
Accepted on repeat testing of same sample without reactivation	4

The application of the above recommendations to production of poliomyelitis vaccine should result i product essentially free of live virus. With negative sults at the recommended test volumes in two conse tive tests during initial inactivation, or following a sir reinactivation period for each single-strain pool, with a third negative on the trivalent pool, final v cine should contain 5 or more tissue culture infect units per liter less than once in 100,000 times. Ad tional operational refinements can also be added the routine production of the vaccine, which should sult in further improvements in product, lessening costs, and no loss of safety. These suggestions, wh have been discussed with the manufacturers at leng include: the substitution of less virulent type 1 stra for the Mahoney strain, control tests to document sensitivity of the tissue culture for virus particulat concentration of the viral suspension before applying safety tests, the conduct of the safety tests themselv and modification of physical arrangements during pr essing.

EPIDEMIOLOGICAL EXPERIENCE, APRIL TO JUNE, 1955

When, on April 25, the first report was received of a case suspected to be poliomyelitis in a vaccinated child, a medical officer from the Communicable Disease Center of the Public Health Service was dispatched to participate in an epidemiological study of the case. During the 1954 field trial, personnel of the Center's Epidemic Intelligence Service had participated in the study of illnesses occurring in both vaccinated and control groups, under the direction of Dr. Francis. In anticipation of the need for epidemiological studies of poliomyelitis in the 1955 program, the Public Health Service, prior to April 12, had planned a small surveillance program to assist state health departments in the follow-up of cases. On April 28, this program was established as a Poliomyelitis Surveillance Unit on an expanded scale, with instructions to devote full time to the rapid identification of cases of paralytic poliomyelitis in vaccinated children and to conduct thorough epidemiological studies of each case. This nationwide epidemiological investigation of poliomyelitis cases associated with vaccination will continue in operation throughout 1955. It is made possible by the collaboration of state and local health officials, private physicians, and the directors of numerous public and private laboratories, with the field and headquarters staff of the Public Health Service. The data that follow are derived from the daily reports of the Poliomyelitis Surveillance Unit through May 31, 1955. This information has been an important factor in guiding our decisions and actions with respect to the vaccination program. Since many cases are still under investigation, some of these figures are subject to confirmation or change.

TABLE 7.—*Relation of Tissue Culture Test Results in Single Strain and Polyvalent Pools—Laboratory B*

	Positive, then after re-inactivation, negative.	6	3	9
	Total	29	3	32

Poliomyelitis Associated with Vaccination.—Table 8 shows the numbers of paralytic and nonparalytic cases of poliomyelitis associated with the product of each manufacturer whose materials have been used since April 12. Attack rates, based on the approximate number of recipients of each product, are shown. A total of 114 cases, with five deaths, had been reported from April 25 through May 31, occurring among approximately 5,500,000 persons within one month after injection of poliomyelitis vaccine. Of these cases, 78 were paralytic and 36 nonparalytic. The largest number of cases and the highest attack rate occurred among approximately 409,000 recipients of vaccine produced by the Cutter Laboratories. Sixty-one per cent of all cases and 76% of the paralytic cases have occurred in Cutter vaccines, with an attack rate of 17 per 100,000 in one month, as contrasted with rates of 1 per 100,000 or less in the four remaining groups. Forty-nine of the Cutter-associated cases occurred in California and Idaho. The remaining 20 cases associated with this product have developed in 15 other states throughout the country.

Among approximately 5 million persons who have received the products of four other manufacturers, 45 cases had been reported as of May 31. Twenty of these were paralytic. The 10 paralytic and 20 nonparalytic cases associated with the Eli Lilly product have occurred chiefly in southeastern and southwestern states where poliomyelitis was occurring spontaneously. The 11 Wyeth-associated cases have been reported from midwestern and eastern states. The two cases associated with Parke-Davis material were reported in Illinois, and the two Pitman-Moore-associated cases were reported in Nebraska. It must be emphasized that association does not necessarily mean a cause-and-effect relationship.

TABLE 8.—*Cases and·Attack Rates in Individuals Receiving Poliomyelitis Vaccine, with Onset April 20-May 21, 1955*

Vaccine Manufacturer	Approximate No. of Persons Receiving Vaccine	Cases			Total Attack Rates per 100,000 per Month
		Paralytic	Non-paralytic	Total	
Cutter	409,000	59	10	69	17
Lilly	2,514,000	10	20	30	1
Wyeth	776,000	7	4	11	1
Parke-Davis	1,234,000	2	0	2	1
Pitman-Moore	461,000	0	2	2	1
Totals	5,394,000	78	36	114	2

Numbers of Cases Reported and Numbers Expected.—There is general agreement that cases of poliomyelitis may be expected to occur, by coincidence, following vaccination because the vaccine will not be absolutely effective and because it will be given to some children who harbor the virus and do not have apparent poliomyelitis at the time of vaccination. Table 9 presents an attempt to determine whether cases among children vaccinated in the 1955 program have been more common than would have been expected by chance. The ages of the first-grade and second-grade children who received vaccine in the National Foundation clinics are known with sufficient accuracy to calculate the numbers of expected cases. Data supplied by the Foundation also make it possible to determine the geographical areas in which these children were vaccinated, as well as the sources of the materials injected. It is not possible, however, to compare the poliomyelitis experience of these children with the current experience of unvaccinated 6, 7, and 8-year-olds in the same geographical areas. A very high proportion of children in these age-groups have received vaccine, leaving virtually no "control" group for com-

TABLE 9.—*Reported Versus Expected Cases in Children Receiving Poliomyelitis Vaccine in National Foundation Clinics*

Vaccine Manufacturer	Approximate No. of Persons Receiving Vaccine (Foundation Clinics)	No. of Poliomyelitis Cases, from April 20-May 21	
		Reported	Expected
Cutter	309,000	35	5
Lilly	2,514,000	28	24
Wyeth	776,000	11	2
Parke-Davis	834,000	2	3
Pitman-Moore	411,000	2	2

parison. Expected numbers, therefore, have been calculated by applying the five-year (1950-1954) median attack rate in 6, 7, and 8-year-olds in the specified geographical areas to the numbers of first-grade and second-grade children vaccinated in 1955 in the corresponding areas. This is a crude measure, for the incidence of poliomyelitis varies widely and unpredictably in successive years; but it is the best tool available under present conditions. The sevenfold increase of poliomyelitis cases over expected incidence in children vaccinated with Cutter materials is statistically significant. However, the marked year-to-year variations observed in attack ratio in any given locality and the small number of cases related to the Wyeth product preclude an accurate interpretation of the data. The numbers related to the Wyeth product are too small to permit accurate interpretation. The numbers of cases reported among children who received vaccines made by Eli Lilly, Parke-Davis, and Pitman-Moore were within the range expected by chance occurrence.

Evidence Related to the Presence of Infective Virus.—The data accumulated by the Poliomyelitis Surveillance Unit support the hypothesis that the excess cases among individuals vaccinated with Cutter material resulted from the use of some lots of vaccine containing infective virus. No other cases of poliomyelitis had been reported in Idaho and in some of the California areas, and this created a suspicion that there might be active virus in some of the vaccine. This suspicion has been buttressed by data on the time intervals between inoculation and onset of paralysis; by a close correlation between the site of inoculation and the site of first paralysis; by the occurrence of poliomyelitis in household associates of vaccinated children; and by the isolation of poliomyelitis virus by one laboratory, from a lot produced by Cutter. Table 10 shows the time intervals between inoculation and onset of paralysis in 66 paralytic postvaccination cases, by source of vaccine. It shows also the comparable interval in 32 monkeys experimentally infected with poliomyelitis virus by Dr. David Bodian.[3] The time intervals in Cutter-associated cases ranged from 5 to 20 days, with a median of 9 days. In three-fourths of the cases, first paralysis occurred from 6 to 14 days following vaccination. This finding corresponds with the comparable incubation periods in monkeys infected by intramuscular injection of virus. Moreover, chronological distribution of cases after inoculation of Cutter materials is the same distribution expected in a common-source outbreak after one exposure to the infectious agent.

TABLE 10.—*Poliomyelitis Cases, by Interval Between Inoculation of Poliomyelitis Vaccine and Onset of Paralysis*

Interval, Days	No. of Cases of Poliomyelitis in Persons Inoculated with Vaccine Produced by:				Experimental Data in Monkeys *
	Cutter	Lilly	Wyeth	Parke-Davis	
5-7	8	2	0	0	3
8-10	22	4	1	0	12
11-13	8	0	1	0	9
14-16	9	1	0	1	3
17-19	2	1	1	0	3
20-25	1	1	3	0	2

* Bodian.[3]

Table 11 compares the sites of inoculation and first paralysis in postvaccination cases, by source of vaccine, with the corresponding sites in monkeys inoculated with live virus. The Cutter-associated cases show a hig degree of correlation between the site of inoculation an the site of first paralysis. In 43 of 55 such cases, or 78%, the first paralysis occurred in the same arm or leg that was injected with the vaccine. This finding is strikingly similar to the experimental evidence in monkeys. In contrast, only 1 of 10 Lilly-associated cases shows the same relationship. There are too few paralytic cases associated with Wyeth and Parke-Davis materials to warrant conclusions. A number of poliomyelitis cases have developed among parents and siblings of va children. As of May 31, 50 such cases had been reported, 36 of which were in the families of children vaccinated with Cutter materials. Eli Lilly and Wyeth materials were associated with five and nine family contac cases respectively. Forty-one of these cases were reported as paralytic, with three deaths. They are distributed among sources of vaccine as follows: Cutter 29; Lilly, 5; and Wyeth, 7. About half of the cases ha occurred in parents and half in siblings. No vaccinate children in these families had contracted paralytic polio myelitis, but about one-third of them had a minor illnes within two weeks after inoculation and prior to the of poliomyelitis in other members of the family.

* Bodian, D.: Unpublished data.

Isolation of Virus.—Type 1 poliomyelitis virus been isolated from more than 20 cases in children v cinated with Cutter materials and from 2 associated w the Wyeth product. Type 2 virus has been isolated fr one case and type 3 from another, both associated w Lilly materials. Laboratory work on postvaccinat cases is in progress, and other isolations no doubt be reported. Dr. Louis P. Gebhardt, department bacteriology, University of Utah College of Medicine an independent study, has reported the isolation of t 1 poliomyelitis virus from a vial of vaccine produced the Cutter laboratory and issued in one of the lots as ciated with paralytic cases in children vaccinated w this material. Extensive studies of all lots issued by t manufacturer are in progress at the National Institutes Health and other outside reference laboratories and ha not yet been completed. The Public Health Service fi report on the Cutter plant and vaccine will be made wh vaccine tests are completed.

"Provocation" Phenomenon.—In our investigation postvaccination cases, we have considered the hypothes that involvement of the central nervous system may b precipitated by intramuscular injection of vaccine in

---

[3] Bodian, D.: Viremia in Experimental Poliomyelitis: II. Viremia and the Mechanism of the "Provoking" Effect of Injections or Trauma, Am. J. Hyg. 60:358-370 (Nov.) 1954.

dividuals already infected with poliomyelitis virus. Had this hypothesis been applicable, one would have expected the excess paralytic cases to occur in areas known to be experiencing some poliomyelitis, such as the southern states. The excess cases did not adhere to this pattern; instead they occurred unexpectedly in Idaho, where no cases other than those associated with the Cutter product were observed. Excess cases did not occur in the southern states up to May 31, where a very large number of children were vaccinated with the product of Eli Lilly, at a time when poliomyelitis was known to be present. Thus, available data do not support the "provocation" hypothesis as an explanation of excess of paralytic cases in areas where Cutter materials were used.

EPIDEMIOLOGICAL CONSIDERATIONS FOR THE FUTURE

The current shortage of poliomyelitis vaccine will undoubtedly continue for some months to come. There is no question, however, that increasing amounts will be prepared; all of the licensed firms have indicated their desire to continue production under the amended requirements. During the period of short supply, physicians can be expected to limit the use of the vaccine to children in the most susceptible age groups, and parents must be satisfied to have it so used. The decision of whether to vaccinate an individual, or to vaccinate during the period of peak incidence, or to vaccinate during local epidemics of the disease rests with the physician and health officer. State and local health officials also should give advice, based on their knowledge of the local, state, and nation-wide prevalence of poliomyelitis. The role of the Public Health Service is related to standards of purity, potency, and safety of the vaccine, to epidemiological studies of the disease, and to the issuance of recommendations on vaccination problems when appropriate. There can be no doubt that the use of the vaccine this season will prevent a high percentage of paralytic poliomyelitis cases in vaccinated children in the age groups identical with those studied in the field trial. For every vaccinated child who contracted paralytic poliomyelitis in the placebo-control areas during the 1954 field trials, three to four children in the placebo groups experienced paralysis.[4]

It must be emphasized, however, that the only substantial data on the effectiveness of the vaccine in preventing paralytic poliomyelitis are limited to children 6 to 9 years of age. Dr. Salk has presented data showing that children under age 6 developed antibodies after vaccination. The relationship between antibody development and protection against paralytic poliomyelitis is still under study. The field trial provided no data upon which to estimate the degrees of protection following vaccination of children under 6 and over 9. Although the data show substantial protection among vaccinated children in the placebo areas, they also show that the degree of protection afforded the children decreased progressively with their age. The downward trend from 9 to 6 years was striking, and the 6-year-olds received little protection. The latter observation, however, may be related to observation of too small a group.

When it becomes possible to use the vaccine in children of age groups other than 5 to 9, it is hoped that careful epidemiological studies will be made to determine the effectiveness of the vaccine in children at younger and older age levels than those who were studied in 1954. Experience with other prophylactic agents indicates that satisfactory procedures for the control of a disease evolve progressively. For example, no substantial control of diphtheria was possible until a satisfactory prophylactic for use in infants and young children had been perfected and effective methods for its application had been developed. This development occurred over a period of many years. This is not to suggest that we shall be so long in perfecting our procedures for the control of poliomyelitis. There are, however, many gaps in our knowledge of poliomyelitis vaccine application. Optimum dosage, time interval between injections, the duration of immunity after vaccination, and the possibility of combining the vaccine with other prophylactic agents and adjuvants are a few of the problems that must stay under constant study with respect to this vaccine. Current research in Dr. Salk's laboratory and many other institutions may make important contributions to the control of poliomyelitis in the next few years. Studies in virology and immunology, not directly related to the vaccine, will have an important bearing on control of the disease. Much is being learned about the mutations of viruses. Moreover, work is in progress on poliomyelitis vaccine produced by a different method of inactivation, as well as on attenuated virus vaccines. Although it is too early to evaluate these new developments in terms of clinical use, they serve to remind us of the essentially dynamic nature of medical science. The development and use of the Salk vaccine has opened the door on a new period in the control of poliomyelitis. Continuing research and observation will surely lead to further improvements and to eventual control of the disease. American medicine and public health have been capable of taking advantage of new medical discoveries in the past. There is no reason now to doubt that they will not take full advantage of the new opportunities afforded preventive medicine by the development of a poliomyelitis vaccine by Dr. Jonas Salk.

SUMMARY

It is erroneous to assume that absolute safety can be assured, but it is believed that recently amended requirements for manufacture and safety testing of poliomyelitis vaccine assure the production of potent material that is safe, as tested by present tests for active virus detection, and that the risk of such vaccine transmitting poliomyelitis is negligible. Vaccine produced by four licensed manufacturers has been used in approximately 5 million children in 1955 with no untoward results. A total of 114 cases of poliomyelitis have been reported in vaccinated individuals through May 31. Of these, 79 were associated with the product of one manufacturer, which had been used in a total of approximately 409,000 per-

---

sons. The widespread use of the poliomyelitis vaccine can be expected to prevent a high percentage of paralytic poliomyelitis cases, especially in children 6 to 9 years of age, and probably in other age groups as well, when supplies become available. It is believed that children younger than 6 years, children older than 9, and adults should receive the vaccine and that studies should be made to ascertain its preventive value against paralytic poliomyelitis in these age groups. Additional experience with the vaccine in the hands of private practitioners and public health officers will lead to further improvements in the control of poliomyelitis. Final decisions on the use of the vaccine remain the responsibilities of individual physicians and health officers.

1954 POLIOMYELITIS VACCINE FIELD TRIAL

PLAN, FIELD OPERATIONS, AND FOLLOW-UP OBSERVATIONS

Thomas D. Dublin, M.D., New York

Early in 1953 Salk reported that a formaldehyde (Formalin)-treated virus vaccine, prepared in his laboratory, had produced neutralizing antibodies against all three types of poliomyelitis virus in children who possessed no demonstrable circulating antibodies against these viruses before vaccination.[1] This trivalent vaccine appeared to be noninfectious; inoculation of human subjects was free of untoward reactions. Moreover, the method of inactivation with formaldehyde, developed at the University of Pittsburgh Virus Research Laboratories, appeared to provide a wide margin of safety in dissociating virus infectivity from its antigenic properties. Inactivation proceeded as a first order chemical reaction, thus permitting ready standardization and rigid control. Experiments in progress gave promise of the early development of even better antigens, capable of inducing persistently high levels of neutralizing antibodies comparable to those observed in individuals who had experienced naturally occurring infection and clinically recognized disease.

Immediately after publication of this report, a distinguished group, aware of the social as well as the scientific implications of these observations, concluded that only a meticulous and systematic extension of Dr. Salk's work could adequately determine the effectiveness of the experimental vaccine under conditions of epidemic exposure. The recommendations of this group, supported by editorial comment in THE JOURNAL,[2] were set forth in an open letter to the medical profession, signed by Dr. Thomas M. Rivers, director of the Hospital of the Rockefeller Institute for Medical Research.[3] The step-by-step plan and time table outlined in this letter provided the guide lines to which the National Foundation for Infantile Paralysis has rigidly adhered in the field trial of the vaccine. In advance of the 1953 season Salk had administered the vaccine to approximately 600 individuals, of whom 474 were children between the ages of 4 and 12. None contracted clinical poliomyelitis during the season of observation; seven were known to have been exposed to the disease through intimate contact, and three of these seven may be presumed to have been infected as a subsequent rise in circulating antibody titers was detectable.[4] Salk's observations followed closely upon other notable advances in the understanding of the pathogenesis and immunology of poliomyelitis. In 1949, Bodian, Morgan, and Howe established the existence of at least three distinct types of poliomyelitis virus.[5] Soon thereafter cooperative research in four different university laboratories confirmed these findings. This typing program, sponsored by the National Foundation, suggested that efforts to control poliomyelitis by immunologic means need be concerned only with the three varieties of the virus that had been isolated from human infections.[6]

Concurrently in 1949, Enders and his associates demonstrated that the poliomyelitis virus could be propagated in non-nervous tissue.[7] This not only supported the hypothesis that the virus might multiply elsewhere in the body before reaching the central nervous system but also offered a practical means of growing the virus in tissue culture. This provided a suitable technique for the mass production of virus necessary for large-scale manufacture of the vaccine. Then, in 1952, Horstmann[8] and Bodian[9] independently found poliomyelitis virus circulating for a brief period in the blood during the prodromal stage of disease, thus indicating a possible site for the establishment of an immunologic barrier to the paralytic sequel of infection. In the following year,

The Prophylactic Effect of Human Gamma Globulin on Paralytic Poliomyelitis in *Cynomolgus* Monkeys After Virus Feeding, Am. J. Hyg. **56**: 78-89 (July) 1952.

Hammon established that poliomyelitis antibodies, passively transferred to human subjects by means of gamma globulin inoculations, temporarily enhanced protection against the paralytic form of the disease.[10]

These fruitful explorations led medical authorities serving on National Foundation advisory committees to recommend, in the fall of 1953, that an extensive field trial of the vaccine developed by Dr. Salk be conducted. In the past, other vaccine and immunizing agents had been introduced into general use on less substantial evidence of their effectiveness. Some, even after years of popular acceptance, have failed to demonstrate measurable evidence of efficacy. Others, through trial and error and the expenditure of considerable time, effort, and money had been modified and improved and had gradually established their usefulness in the prevention of acute communicable disease. It was assumed that with the resources of the National Foundation and with the widespread public concern for those afflicted with poliomyelitis a field trial applying modern methods of clinical, immunologic, and epidemiological study could with unprecedented speed establish answers to many unanswered questions. Could the vaccine prepared in the research laboratory be reproduced consistently and uniformly by commercial manufacturers? Would neutralizing antibodies induced by the vaccine protect susceptible individuals against the paralytic forms of the disease under natural conditions of exposure? Would mass use be attended by untoward reactions comparable to the dangers of the disease itself? If such a vaccine was protective, would the immunity artificially induced be complete or partial? Would the strains of virus used in this vaccine induce protection against all strains responsible for the naturally occurring disease? Are the comparatively few individuals who develop paralytic poliomyelitis through natural exposure those who do not respond readily to artificial immunization?

Many additional questions were raised, but it was apparent that none could be conclusively answered without crucial studies conducted on a scale sufficient to obtain statistically valid evidence. Some questions, concerning, for example, the duration of protection, would require long-term study. Most questions, however, seemed capable of answer within a one-year undertaking. The following objectives were therefore established for the field trial: (1) to determine whether a formaldehyde-inactivated trivalent poliomyelitis vaccine would offer protection against naturally occurring paralytic poliomyelitis to a selected group of children during the poliomyelitis season next following vaccination, and if protection is provided, the degree of such protection; (2) to determine what, if any, levels of actively induced antibodies are associated with subsequent resistance to paralytic disease; and (3) to observe the nature and incidence of untoward reactions to the vaccine. In mid-November, 1953, the National Foundation announced that the field trial would be initiated prior to the 1954 poliomyelitis season. The program, under the over-all supervision of Dr. Hart E. Van Riper, medical director of the National Foundation, was to be guided by advisory groups drawn from the National Foundation's own committees on research and professional education and by other committees designated by the Association of State and Territorial Health Officers.

Three phases were established for the field trial. The first concerned the planning of the entire operation and included the preparation, by cooperating manufacturers of biological products, of the large amount of vaccine that was needed. This phase began to accelerate in the summer of 1953 and continued beyond the actual start of inoculations in the field in late April, 1954. The Connaught Laboratories of the University of Toronto, Toronto, Canada, was enlisted to develop mass-production methods for the cultivation of virus in high concentrations by using monkey kidney tissue culture techniques. A group of American manufacturers, with extensive experience in the preparation of vaccines, were then recruited to undertake inactivation of the virus and actual production of the vaccine. Five such manufacturers agreed to participate on a nonprofit basis in this phase of the program. Two—Parke, Davis & Company of Detroit and Eli Lilly & Company of Indianapolis—succeeded in overcoming the many production problems and in meeting the rigid safety requirements in time to permit the use of their vaccine in the actual inoculation phase of the field trial.

The second or operational phase of the field trial gained momentum in the early fall of 1953 and reached a maximum of intensity in late April, May, and June, 1954, when inoculations were given. Technically speaking, the third or evaluation phase might be considered as beginning with the submission of completed reports to the evaluation center. However, no sharp line can be drawn between field operations and evaluation. Initially, the National Foundation itself supervised and coordinated field activities but even as the test materials—vaccine and placebo—were being administered to children in the schools, Dr. Thomas Francis Jr., and his group at the poliomyelitis vaccine evaluation center at the University of Michigan, Ann Arbor, assumed responsibility for supervision of the follow-up of those taking part in the trial and for collection and collation of case reports and other data essential to the preparation of the evaluation report.

Dr. Francis has previously presented summary findings of his evaluation study.[11] The decision to enlist Dr. Francis and to establish the evaluation center was predicated on the unquestioned need for an objective, independent evaluation of the vaccine. That this has been achieved is abundantly clear to all who have examined the summary report. Francis's report stands not only as a remarkable tribute to Dr. Francis and his immediate staff but also to literally thousands of practicing physicians, nurses, physical therapists, public health and school personnel, workers in collaborating laboratories, and the general public who cooperated in and contributed to its preparation.

DESIGN OF STUDY

From the very beginning of the field trial it was recognized that a study of considerable size would be necessary if the effectiveness of the vaccine was to be measured. As is well known, the risk of poliomyelitis attack has been extremely small as compared with many other disease entities. During the 10-year period 1943-1952 national poliomyelitis case rates averaged only 18.5 per 100,000 population. Moreover, interannual variations in incidence in the United States have ranged during the last 15 years from a low of 3.1 in 1942 to a high of 37.2 in 1952 (fig. 1). The unpredictability of epidemic poliomyelitis in any given community in any given year is also well recognized. Because of these and other known epidemiological characteristics of the disease, a decision was reached to conduct the field trial on a nationwide basis, provided the cooperation and assistance of state and local authorities and of the public could be obtained. Communities would be selected according to geographical and socioeconomic factors so as to provide a representative cross section of the United States population. It was also agreed that preference would be given to communities where the maximum number of cases might be anticipated during the study year and to those communities where health and educational resources would permit the satisfactory conduct of the trial.

Early in the planning of the field trial, sharply divergent views were expressed in the selection of a control population against which the effect of the vaccine on those inoculated would be measured. Some held that the effectiveness of the vaccine could be measured only if a control population identical in all respects except for vaccination, and matched individual for individual with those immunized, was available. To meet these requirements it would be necessary to inoculate one-half of the study population with the vaccine and the other with an inert material or one known to have no effect on the occurrence of paralytic poliomyelitis. In addition, the identity of the inoculated solutions would be masked by coded designations to be deciphered only after all observations had been completed and final analysis of results was in process. The difficulties inherent in carrying out such a placebo control study were acknowledged, but the proponents of this plan were confident that the advantages in terms of objectivity and ease of analysis far outweighed its disadvantages.

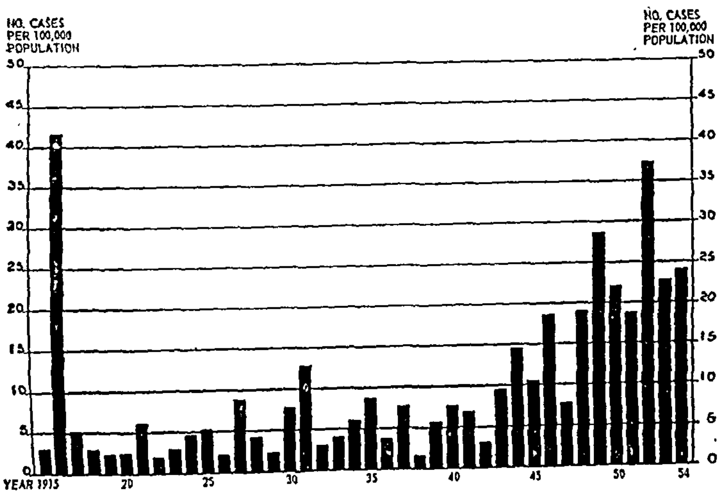

Fig. 1.—Reported poliomyelitis cases per 100,000 population in the United States, 1915-1954. The population was estimated in midyear by the Bureau of the Census. Data for 1954 were provisional. All data were taken from the U. S. Public Health Service.

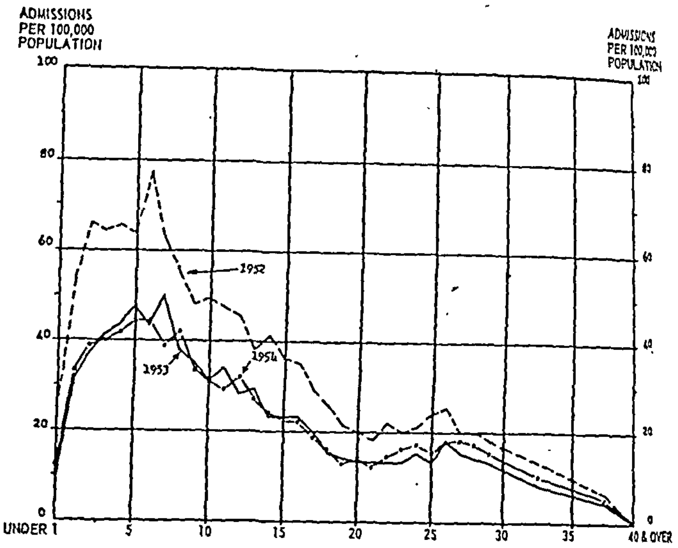

Fig. 2.—Poliomyelitis age specific acute admission rates per 100,000 population for 1952, 1953, and 1954. Population estimates are for mid-1952, mid-1953, and mid-1954. The 1952 rates are based on 35,882 notices of original acute admissions received July 20, 1952, through Jan. 31, 1953. The 1953 rates are based on 23,698 notices of original acute admissions received January through December, 1953. The 1954 rates are based on 24,950 notices of original acute admissions received January through December, 1954.

An observed control study was advanced by others as more desirable since its administration was far simpler. This plan would offer vaccine to all who volunteered to receive it. In the opinion of its proponents the effectiveness of the vaccine could be measured by comparing the incidence of paralytic poliomyelitis in those inoculated with that experienced by individuals of the same or comparable ages under similar conditions of exposure. Those proposing this plan of study discounted the likelihood of differences in attack rates arising purely as the result of selection of vaccinated and unvaccinated subjects or that unintentional bias might occur in the recording of illness in the two groups. Both plans of study were adopted; the choice of a placebo control study or an observed control study was left to the discretion of the responsible health officer of each state. Subsequent studies have indicated some of the selective factors that might affect the incidence of paralytic poliomyelitis in inoculated as opposed to observed control children.[12]

DETERMINATION OF COMPOSITION AND SIZE OF STUDY POPULATION

Since the degree of effectiveness of the vaccine was itself at test and since no reliable prediction of poliomyelitis incidence in the study population during the study period could be made, it was most imperative that the composition and size of the study group enhance the probability of statistically valid observations. On the other hand, time available for inoculations, limited supply of vaccine, and other factors exerted restrictions on the scope of the project. Although the age distribution of poliomyelitis has changed in the United

States in recent years, it remains essentially a childhood disease. Almost 75% of reported cases occur under age 20 and over 50% in children under 10. The peak ages of clinically diagnosed poliomyelitis occur in the years immediately before and after entrance into primary school (fig. 2). This fact and the accessibility of school children in organized groups for vaccination determined the selection of children enrolled in the first three grades of primary school as the study population. Enrollment in these classes roughly corresponds with the age band 6 through 9 in which, on a national basis, at least one out of five of all reported cases might be expected to occur.

In addition, it was possible, utilizing the annual incidence rates of reported poliomyelitis for the United States, to estimate, on theoretical grounds at least, the probable minimum size of the study population required to give statistically valid results. Based on such analyses, it could be anticipated that if in the field trial areas a low incidence rate of paralytic poliomyelitis was encountered and the vaccine were only 50% effective, it might be necessary to vaccinate almost 700,000 children (and observe an equal number of controls) before valid findings could be obtained. If on the other hand, the vaccine should prove 80% or more effective and an "average" poliomyelitis year occur, a high level of certainty of the results could be derived from a study of fewer than 100,000 subjects equally divided between vaccinated and controls. A conservative approach dictated that a practical goal be set for the inoculation of between 500,000 and a million children.

TABLE 1.—*Poliomyelitis Crude Case Rates, by Size of County, 1948-1952*

Population Class, Thousands	No. of Counties	1950 Total Population, Millions	Reported Poliomyelitis Cases, 1948-1952 Total	Av. Annual No.	Av. Annual Rate per 100,000
Total, all counties	3,103 *	150.7	189,072	37,814	25.1

† Includes District of Columbia, Baltimore, and St. Louis; excludes the cities of Norfolk and Richmond, Va.

SELECTION OF FIELD TRIAL AREAS

Earlier studies [13] cast doubt upon the possibility of selecting specific areas that might be expected to experience epidemic conditions during the field trial. On the other hand, the observations of Benjamin and Logan in England and Wales [14] offered encouragement that a group of areas with high prevalence in the past might yield higher-than-average attack rates in a subsequent year. In a report awaiting publication Stickle [15] confirmed these findings in studying poliomyelitis incidence in the more than 3,100 counties in the United States. Summarizing Stickle's findings, it became apparent that counties with a population of 50,000 to 200,000 experienced a significantly higher average annual attack rate than those with a population of over 200,000. Interestingly and consistently the recorded incidence of reported poliomyelitis is highest in counties with populations under 50,000 and yet, in general, it was necessary to omit these smaller jurisdictions from further consideration (table 1). Public health and medical resources requisite for the trial were less readily available in the smaller areas. Further analyses indicated that intercounty variability in case rates was more than three times that of year-to-year variance within counties and that counties with the highest average attack rates have, in the aggregate, a substantially higher than average attack rate one and two years later.

On the basis of such analyses, it seemed justified to recommend the participation of those counties of 50,000 to 200,000 population reporting the highest average attack rates during the five year interval 1948-1952, the latest period for which data were available. This preliminary method of selection did not exclude some larger and some smaller counties where it seemed both desirable and feasible to include such areas. In the extensive discussions that followed, several supplementary criteria for selection were developed. For example, preference was given to areas with well-organized health services capable of conducting effectively the operational and follow-up phases of the field trial, and where the interest and cooperation of local health and school authorities and the willingness of parents to request participation of their children in the test were overtly manifest. One additional criterion was important in the final selection of field trial communities. Areas experiencing significant outbreaks before the start of inoculations were to be excluded. This was considered desirable in order to avoid, as far as possible, any fortuitous association of inoculations with the onset of cases.

The final result of these considerations was the joint selection by the National Foundation and state health officers of 217 areas in 44 states. Placebo control studies were conducted in 91 areas in 11 states and observed control studies in 126 areas in 33 states. Before inoculations were begun in late April, 1954, the number of areas expected to participate was somewhat larger. However, Maryland, Arizona, and the District of Columbia withdrew because of inability to complete the inoculation program prior to the closing of schools. All three field trial areas in Georgia were excluded at the last moment because of the occurrence of cases of paralytic poliomyelitis in the period immediately preceding inoculations. Minnesota authorities failed to sanction the program within that state in time to permit the necessary preparations. Because of interest in the program outside of the United States and the desire to add as many trial areas as time and materials would permit, 46 areas in three Canadian provinces—Alberta, Manitoba, and Nova Scotia—took part in the trial; two small areas in Finland also were included. In 1954, the areas included in the field trial in the United States experienced a reported case rate of 28.9 per 100,000 population, which was 26% higher than the rate in nontrial areas. Thus the criteria for the selection of participating trial areas actually fulfilled expectations in maximizing the number of cases in the test population.

[15] Stickle, G.: Statistical Criteria for the Selection of Poliomyelitis Vaccine Field Trial Areas, to be published.

ORGANIZATION AND ADMINISTRATION OF FIELD ACTIVITIES

It was apparent from the outset that large numbers of individuals with varying professional skills and other competences were needed if the test was to be successful. The majority of these individuals were volunteers recruited in the local field trial areas. It is estimated that more than 300,000 persons — including physicians, nurses, school teachers, public health and school officials, and community volunteers recruited by National Foundation chapters and by other civic, fraternal, or service organizations—cooperated in this extraordinary medical undertaking. Glasser has already summarized an able manner how volunteers were recruited and ectively utilized in many of the community phases of field trial.[16] Organization in each community centered around the schools where children who were to take part in the field trial were enrolled. Classroom teachers and volunteers shared in the school room census and registration of the study population, in the handling of parental request forms, in the basic education and preparation of children and parents for the test, and in the guidance of children to and from the vaccination clinics. For the most part, inoculation of children took place in school clinics; however, where the number in a given school was small, or where it was otherwise advantageous to do so, larger and centralized clinics were held elsewhere in the community. Coordination of activities in the schools was channeled through the school principal to the local health officer. In the absence of a local health officer, a qualified practicing physician served as the director of the local field trial program. It was the responsibility of the local director to enlist local interest and support for the program, to recruit the necessary physicians and other professional staff, and, with the aid of volunteers supplied by the local chapter of the National Foundation, to attend to the infinite number of etails required by the program.

Within each state, the state health officer assumed over-all responsibility for the program. Participation in the field trial was, in general, predicated upon his prior consultation with state educational authorities, the state medical society, and such local groups in the prospective field trial areas as might be indicated. The state office staffs of the National Foundation and its regional representatives were placed at the disposal of state health departments to assist them in the many specialized tasks required. Though freedom to adapt the program to established local practices was permitted, each state agreed that uniformity of procedures and forms would be maintained, the publicity regarding results of the vaccination study would not be made independently, and that analysis of the data collected would be left exclusively to the evaluation center. There was universal understanding at all operational levels that publication of the results of the trial would be made only by the evaluation center when, in the opinion of Dr. Francis and his advisors, such would be justified.

Within the National Foundation itself, only a small coordinating staff was assembled, for the most part drawn from the various operating departments of the headquarters office. Under the direction of Dr. Van Riper, this group served as staff for the various advisory committees and provided liaison with the laboratories and manufacturers engaged in the preparation of the vaccine. In addition, it collected and analyzed essential statistical data, assisted state health departments in the selection and preparation of communities for field operations, and prepared educational and instructional materials and record forms for use in the field. Other departments of the National Foundation, particularly those dealing with its 3,100 local chapters and with public relations, were also intimately involved in the program. A major function of the National Foundation was to develop the interest and support of professional groups in the health and education fields and of civic, fraternal, and service clubs.

STANDARDIZATION OF PROCEDURES

So that each state and community taking part in the field trial would complete each step in a standardized manner, a Manual of Suggested Procedures was prepared.[17] Addressed primarily to the local health officer, the manual outlined the basic principles and policies of the field trial, defined functions and responsibilities of those participating in it and explained the procedures to be followed in each community. In addition, it described the record forms, educational materials, and supplies to be furnished by the National Foundation to each community. Supplements to the manual, in the form of operational memorandums, were also prepared so that physicians in charge of vaccination clinics, school principals, classroom teachers, clinic recorders, and others would have available to them relatively brief check lists of their tasks and assignments. As vaccinations proceeded, Dr. Francis issued a series of memorandums specifying the manner in which all records were to be handled. These memorandums also outlined the steps to be followed in the identification, study, reporting, and follow-up of each illness occurring in members of the study population, whether in a vaccinated child or not. A regular channel of communication was maintained between the evaluation center and the responsible health officers in each field trial area. Special effort was made to acquaint those th administrative responsibilities in the study areas :h need for completeness, accuracy, and uniformity of records that were to be forwarded to the evaluation nter and ultimately provide the data essential to an jective appraisal of the vaccine.

[16] Glasser, M.: M Day for Polio, Adult Leadership 3:5-7 (Sept.) 1954.

[17] Manual of Suggested Procedures for the Conduct of the Vaccine Field Trial in 1954, New York, National Foundation for Infantile Paralysis (March) 1954.

RECORD KEEPING AND IDENTIFICATION OF THE STUDY POPULATION

All children enrolled in the first, second, and third ades of public, private, and parochial schools in the 7 field trial areas comprised the study population. ıly by enumerating all members of this study populaın was it possible to determine accurately whether an dividual experiencing poliomyelitis during the period investigation belonged in the vaccinated or control oups and to calculate attack rates for the different tegories of the study population. This basic enumeraın was accomplished by use of registration schedules orm FT-3) that were completed for each of the three ades in every participating school. Each sheet and ıe was numbered uniquely, permitting permanent idenication of each child by name, address, school, grade ıte of birth, sex, race, previous history of poliomyelitis, ıd presence or absence of muscular disability. These hedules were completed in the early preparatory phase : the trial; subsequent entry of additional information ertaining to inoculation and the collection of serologic ecimens was made on the registration schedules. Parcipation in the field trial was voluntary; no child reived inoculation, vaccine or placebo (solution 199), ıless a parent so requested in writing. Permission was so sought for the collection of blood specimens for ntibody determinations, if needed. The parents of each ıild in the study population received a printed parental :quest form (forms FT-1 and FT-2) through which ıey might request participation of their child in the eld trial. Return of a signed form was no guarantee that ıe child would be inoculated with the vaccine. A surrisingly high proportion of parents, over 50%, asked ıat their children be included in whatever measures, ıoculations, and/or collection of blood specimens, were ecided on for them.

A vaccination record (form FT-4) was filled out for ach child who received an inoculation or from whom lood was taken. It recorded the date of each of the hree intramuscular inoculations of 1 cc. each at 0, 1, nd 5 weeks, respectively, the lot or code number of the naterial given, the name of the physician giving the inoculation, and the dates blood specimens, if any, were lrawn. Space was provided for recording any evidence of reactions. If the series of inoculations was not completed, the reason was stated. Information on the vaccination record was transcribed to the registration schedule, thereby permitting a check for accuracy and inconsistencies. Registration schedules and vaccination ecords were prepared in triplicate. They were edited ocally and the first two copies sent to the state health department. Then, after review, the original copies were orwarded to the evaluation center for processing.

Collection of Blood Specimens.—Two other elements of the early field operations deserve mention. One involved the collection of blood specimens for neutralizing antibody determinations and the other the observation of vaccinated children and suitable controls for the occurrence of any untoward reactions that might be associated with the vaccine. The field trial offered an unusual opportunity to extend the earlier and limited observations of Salk with respect to the antibody response of human beings to the vaccine. After careful consideration, it was decided that three serial samples of blood would be sought from at least 2% of both vaccinated children and controls. These samples were collected at the time of initial inoculation, two weeks after the third inoculation and again at the conclusion of the poliomyelitis season, that is, approximately six months later. Almost 42,000 samples were collected at the first bleeding, over 34,000 at the second, and approximately the same number at the third. These and the following figures vary slightly from those appearing in Dr. Francis's summary report.[11] The data presented here are based upon preliminary tabulations submitted from the field to the National Foundation by state health officers; the records utilized and reported by Dr. Francis were subject to extensive editing and retabulation after the original records were submitted to the evaluation center.

At the time this plan was developed, only a few laboratories were in a position to undertake studies on the scale projected and only a small number had had experience in the extensive serologic tests contemplated. Nevertheless, 28 laboratories widely distributed geographically were recruited in a brief period of time to handle this vital phase of the investigation. In addition these laboratories participated in the equally important task of serologic study of and virus isolation from cases occurring in the study population.

Observation of Untoward Reactions.—An analysis of the incidence and nature of reactions associated with the vaccine was an integral part of the field trial. Between May 16, 1953, and March 9, 1954, Dr. Salk had inoculated 5,320 individuals with vaccine prepared in his own laboratory without causing any recognizable untoward effects upon the recipients, many of whom had received several inoculations. In addition, in the period immediately preceding the field trial, Dr. Salk had administered the commercially produced vaccine to be utilized in the field trial to 7,507 children. Of these, 3,097 had been observed for more than 21 days and 3,443 had been inoculated with vaccine at an earlier date. Again, no reactions were encountered with the single exception of transient urticaria in a child reported to be sensitive to penicillin. Some concern, however, was expressed lest nephrotoxic reactions, associated with the minute quantities of kidney tissue protein present in the vaccine, or Rh sensitization related to the inoculation of material containing minute quantities of monkey kidney, might represent genuine dangers to the mass use of the vaccine. Kumm[18] has summarized the careful investigations of such possible reactions that preceded the initiation of the field trial. Additional study of these and other possible untoward effects during the field trial was approached in several ways. The vaccination record made provision for the recording of reactions, and the manual of suggested procedures emphasized the need to record any untoward effects that appeared related to or coincidental with the administration of the vaccine. Specific instructions from the evaluation center requested notification by phone of any circumstances of significant severity that might be related to inoculations. In addition, special studies of absenteeism in schools and their causes were undertaken, and further laboratory and clinical investigations of the identifiable elements contained in the vaccine were carried out.

[18] Kumm, H. W.: The Present Status of Vaccines for the Prophylaxis of Poliomyelitis, Illinois M. J. 106: 13-19 (July) 1954.

FIELD OPERATIONS

Initially, the time table established anticipated that inoculations in the field would begin in early February and continue through May, with the program starting in southern states, where the seasonal rise is usually first to appear, and proceeding northward. It was clearly understood, however, that inoculations would not begin until (1) there were assurances that sufficient vaccine would be available to permit a reasonable measurement of its effectiveness, (2) safety and sterility tests of a predetermined and exhaustive nature had been carried out independently on each lot of vaccine by three laboratories—by the manufacturers, by Dr. Salk, and by the Laboratory of Biologics Control of the National Institutes of Health, and (3) Dr. Salk had extended his preliminary pilot study to a minimum of 5,000 human subjects. In addition, the antigenicity of each lot of vaccine produced by manufacturers for use in the field trial would be titrated by Dr. Salk against the response he had obtained with material produced in his own laboratory.

These rigid though essential prerequisites, established by the vaccine advisory committee of the National Foundation, were met on April 25, 1954. This committee then recommended that the nationwide field trial proceed.[19] At that time the U. S. Public Health Service made the following statement: "We believe that the judgment of the Vaccine Advisory Committee is sound and that the National Foundation for Infantile Paralysis is justified in proceeding according to the Committee's recommendations." So that the medical profession would be kept fully informed concerning the background of the field trial and developments as they occurred, periodic releases were prepared for publication in national, state, and local medical journals. Shortly before the actual start of inoculations, each practicing physician in the country received through the mail a special preprint of an article on vaccination against poliomyelitis prepared by Dr. Van Riper.[20]

On April 26, 1954, the first series of inoculations were begun. Altogether, 653,793 individuals in a study population of 1,831,702 children in the United States received first inoculations. One week later 640,668 children began receiving their second inoculations, and five weeks later, 629,063 or over 96% who had received their first began to receive their third inoculations. Because of different starting dates in many of the field trial areas, the administration of vaccine and the collection of the first two blood samples in the 217 field trial areas in the United States continued to about mid-June. Because of later starting dates, this phase of the program continued in Canada and Finland somewhat longer (table 2). In placebo control areas the study required the giving of three matched inoculations of coded material over a period of five weeks to children in the first three grades of school. In fewer than 0.2% of the 421,031 children inoculated did a child receive a mixed series of vaccine and placebo. In observed control areas inoculations were given only to children in the second grade, and 232,762 were given vaccine in this segment of the study population. The negligible amount of confusion and recording errors observed during the inoculation phase can be attributed to the diligence of all those concerned with the field trial and to the supervision given by the evaluation center. During the vaccination period April 26 to June 15, personal visits were made by evaluation center staff to 32 of the 44 participating states.

OBSERVATIONAL PHASE AND FOLLOW-UP PROCEDURES

A crucial element in the field trial was, of course, to determine the occurrence of poliomyelitis in members of the study population. This required the identification of all possible cases; the establishment of correct diagnosis by clinical, epidemiological, and laboratory study; accurate and complete recording of all relevant data in a systematic manner; and the transmission of all required information to the evaluation center at Ann Arbor. The primary responsibility for this fell on practicing physicians in local communities, particularly in the field trial areas, but in other localities as well. Local health officers and, in many states, the staff of the state health departments played an equally vital role in arranging for or actually participating in each of the steps

20. Van Riper, H. E.: Vaccination Against Poliomyelitis, GP 9:59-62 (April) 1954.

essential to the identification, reporting, and investigation of cases. To reduce the need for discrimination locally and to encourage completeness of reporting and uniformity of procedure, a simple plan was devised by the evaluation center. All illnesses arising in any child enrolled in the first, second, or third grade in the spring term in schools located in the field trial areas, whether the child was inoculated or not, were to be investigated. Every case—paralytic, nonparalytic, suspected, or doubtful—was to be reported to the evaluation center and subjected to the same degree of study.

The lucid description given in Dr. Francis' summary report of the record forms, systematic checks and counterchecks, the use of diagnostic consultants and specially trained physical therapists for muscle grading examinations, and the availability of laboratory services and other follow-up procedures makes it unnecessary to review in detail at this time each of the precise steps taken in this phase of the field trial. It is now apparent that the information on 1,103 cases sent to the vaccine evaluation center from May 1 to Dec. 31, 1954, represented as complete a record of poliomyelitis experience in the field trial population during the study period as human ingenuity and competence could devise.

SUMMARY

That an extensive field trial of a poliomyelitis vaccine has been conducted by the National Foundation and many cooperating individuals and agencies has been widely publicized. It is almost universally known that this basically medical test—unprecedented in its objectives, its magnitude, and its scope—has been highly successful, and there is now available to the public a safe and simple measure offering 60 to 90% protection against paralytic poliomyelitis. A few days after the announcement of the results of Dr. Francis's evaluation in Ann Arbor, Mich., on April 12, 1955, a Gallup poll indicated that 96% of all people interviewed in the national sample and 98% of all people with children under the age of 15 had heard about the vaccine. The report indicated that more people knew about the vaccine than had known of almost any news event on which a public opinion poll had ever been taken.[21]

What has been less readily recognized is the step-by-step and painstaking labor that has made our present confidence of mastery over this disease possible. For more than 50 years scientists throughout the world have slowly accumulated better understanding of each of the many phases of this disease, its clinical and epidemiological characteristics, its etiology, its pathogenesis, and its immunologic manifestations. The seemingly disparate elements of a highly complex mosaic began to fit together into recognizable form only when a coordinated attack on poliomyelitis, sponsored primarily by the National Foundation for Infantile Paralysis was launched 17 years ago. Since 1948, the progress achieved by this frontal attack has been rapid and dramatic, and it can be suggested that the preliminary planning for the crucial experiment comprising the 1954 vaccine field trial actually goes back that far. It has been stated by competent authority that the uniqueness of a safe, potent, and effective poliomyelitis vaccine, available for widespread use, is in large measure inherent in the circumstances surrounding it rather than in the preparation itself. For the first time in medical history, a vaccine has been developed as a result of a publicly supported program of medical research.

Uniqueness, also, is intrinsic in the decision of the scientific advisors of the National Foundation for Infantile Paralysis to determine precisely the validity of the vaccine's protective effect. Despite the fact that the vaccine's safety and ability to stimulate the production of specific antibodies had already been established by extensive laboratory, animal, and human being tests, the decision was made to establish its protective effects in a statistically significant group of children under natural conditions of exposure before it was made generally available to the medical profession and to the public. It is possible to reflect now how sound this decision was. Also, unprecedented in medical and scientific history has been the demonstration that literally hundreds of thousands of volunteers—physicians, nurses, physical therapists, laboratory workers, public health and school personnel, and the general public—can be effectively mobilized in a truly scientific endeavor. This achievement required an unusual degree of foresight and imagination, meticulous and deliberate planning and organization at each stage of development of the program, and, finally, the unfaltering confidence of the American public who have made the National Foundation for Infantile Paralysis and its program possible. In the last analysis the field trial has not been an end in itself; it is merely another step, though a great one, in the advance of human understanding of and control over paralytic poliomyelitis.

Accidental Death from Electric Current.—The death rate from accidents involving electric current has decreased over the years. At present, such accidents take about 1,000 lives annually in the United States, or 7 per million population, whereas a quarter century ago the corresponding death rate was 9 per million. Fatalities due to electric current show a distinct seasonal pattern, beginning to increase in the spring and reaching a peak in the summer; more than two fifths of the deaths each year occur in June, July, and August. The higher mortality in summer results largely from increased activity in the repair and extension of electric lines and from the generally greater amount of outdoor work which brings men in accidental contact with electric lines. Moreover, when the body is wet with perspiration, as is often the case in warm weather, its resistance to electric shock is lowered. About 95% of the fatal accidents caused by electric current in the United States occur among males, reflecting largely the effect of occupational hazards. It is not surprising, therefore, that the victims are concentrated principally in the main working ages of life. . . . Somewhat over one fifth of all the males killed by electric current in 1951-1952 sustained their injuries on industrial premises—electric light and power plants, factories, workshops, and similar places. . . . Hazards on the farm have been responsible for an appreciable loss of life from electric shock; the toll was 181 (177 of them males) in 1951-1952. For the most part these fatal accidents involved farm production equipment, such as irrigation pumps, machinery, and electric fences. . . . Accidents in the home accounted for one sixth of the deaths due to electric current among males and for about four fifths of those among females in 1951-1952.—Accidental Death from Electric Current, *Statistical Bulletin Metropolitan Life Insurance Company*, May, 1955.

EVALUATION OF THE 1954 POLIOMYELITIS VACCINE FIELD TRIAL

FURTHER STUDIES OF RESULTS DETERMINING THE EFFECTIVENESS OF POLIOMYELITIS VACCINE (SALK) IN PREVENTING PARALYTIC POLIOMYELITIS

Thomas Francis Jr., M.D., Ann Arbor, Mich.

The purpose of the poliomyelitis vaccine evaluation program in the field trial of 1954 was to seek a measure of the prophylactic effect of the preparations of vaccine to be used, the only assumptions being that the experimental background was sound and that the vaccine was to be antigenic and noninfectious. The undertaking meant the acceptance of a public and scientific trust to provide, so far as possible, an objective analysis and unprejudiced appraisal of data obtained from numerous study areas. It must be fully realized that the evaluation program was not a tightly knit operation carried on by a single group of investigators. Rather, it was a widespread series of investigations that the vaccine evaluation center at the University of Michigan sought to integrate by obtaining uniform acceptance of instructions and procedures and, thus, to maintain uniformity of understanding and performance and completeness and accuracy of investigation and report. In effect, then, the center served as the executive agency for a study dependent upon the willingness, interest, and cooperation of the local medical profession, both administrative and practicing, and of their affiliated personnel. But, in addition, there was the extended network of virus laboratories, geographically distributed, to aid in the specific diagnosis of reported cases; a large number of specially oriented physical therapists who would make detailed examinations of the muscular status of each patient in assigned study areas. Beyond this was the great background of public interest leading to their voluntary participation in an investigation that was, in the end, completely dependent upon their support.[1]

All data from all areas were transmitted to the center on forms devised for the specific step. Throughout the study period the major effort of the staff of the center was concentrated on getting the necessary information from the different agencies responsible for the actual work at the local level. All possible means were used to eliminate delays, inaccuracies, or omissions in the requisite reports, with the result that a high degree of completeness was finally attained.

STUDY PLANS

The evaluation program embraced two distinct plans. The plan originally announced by the National Foundation for Infantile Paralysis was to vaccinate all children in the second grade of school whose parents requested it, while all the children of the first and third grades were to be kept under observation as controls for the vaccinated children. The ease of carrying out vaccination under such conditions recommends the procedure, but it presents possible disadvantages in the evaluation by the ready opportunity for the introduction of bias at any stage in the diagnosis and investigation of cases. The vaccinated persons are those who specifically volunteer; the controls comprise both those who might volunteer and those who would not. The age groups do not correspond, although the first and third grades bridge the second grade in this respect. It can readily be determined whether a child was vaccinated or not, and that knowledge could influence subsequent consideration. Table 1 presents the number of participants in the "observed study areas."

TABLE 1.—*Distribution of Study Population, by Participation Status and Vaccination Status—Observed Areas*

Study Population	No.	% of 2nd Grade	% of Total Population
All grades			
Total	1,080,680	....	100.0
Requests	567,210	....	52.5
2nd grade (requests)	245,895	69.2	22.8
Complete vaccinations	221,998	62.4	20.5
Incomplete vaccinations	9,904	2.8	0.9
Absent or withdrew	13,993	3.9	1.3
1st and 3rd grades (requests)	321,315	....	29.7
All grades			
Participation not requested	332,870	....	30.8
Participation not recorded	180,600	....	16.7

In order to achieve strict impartiality in the study o patients in test and control groups, the second plan o study was introduced. It comprised all children of the first, second, and third grades whose parents requested their participation, with a clear understanding that hal would receive vaccine and the other half a placebo while knowledge of the inoculum was available only by a code held at the evaluation center. Those who received the placebo were the controls and have been shown in all respects to be counterparts of the vaccinated children (table 2). Those who did not participate were not considered additional controls. The uninoculated persons were, however, to be followed in the same manner as the participants; it was also to be true of uninoculated persons in the second grade of observed areas. This was adopted to gain uniformity of investigative procedure without consideration of vaccination status and to avoid selective problems at the local level. But it should be emphasized that those not included as participants are not an integral part of the evaluation; they are a different population. Evidence that they are different was clearly supplied in a survey of the socioeconomic status and

reaction to health problems among families of the ebo study areas. Numerous studies have indicated rences in antibody development and susceptibility oliomyelitis between portions of populations of difnt socioeconomic levels, and the differences demoned in the survey indicated that the nonrequesting ılation might well be a more resistant group than inoculated.

DATA REQUIRED FOR EVALUATION

'he vaccination program was carried out between the of April and mid-June. The first problem was that ollecting and verifying the basic information on each ıe 1,829,996 children in the total study population. ıcluded a record of the lot of material given in each ulation to each child. These data were transferred to hed cards so that tables describing the population ırding to essential characteristics could be prepared. as an extensive but essential task, since it provided necessary identification of the vaccinated and conpersons in whom the incidence of poliomyelitis ld be investigated and the measurement of vaccine's fect would be made. In addition, from more than),000 children of the vaccinated and control groups ımples of serum were obtained prior to the time of inction, together with serums taken two weeks after the inics were completed and again five months later, and ere to be tested in the respective laboratories. These ecords were also established and results received at the enter. From them the distribution of antibody in this egment of the population in different parts of the counry, the response to vaccine, the persistence of effect, and ossibly information on the extent of natural exposure o poliomyelitis virus in the different areas during the tudy period as indicated by antibody changes could be letermined.

.E 2.—*Distribution of Study Population, by Participation Status and Vaccination Status—Placebo Areas*

Study Population	No.	%
otal in grades 1, 2, and 3	749,236	100.0
otal requests to participate	455,474	60.8
Complete series of injections		
Vaccine	200,745	26.8
Placebo	201,229	26.9
Incomplete injections		
Vaccine	8,484	1.1
Placebo	8,577	1.1
Absent at first clinic or withdrew	36,439	4.9
Number not requesting participation	280,868	37.5
Participation status not recorded	12,894	1.7

The second phase in the evaluation was concerned with discovery and identification of all cases of polionyelitis or suspected poliomyelitis in all children of the irst, second, and third grades in the study areas. The various steps in the investigation of a case are: (1) physician's diagnosis—report to local health department; (2) telegraphic report to vaccine evaluation center; (3) iction of local health department, including (*a*) clincoepidemiological investigation and report to vaccine evaluation center, form FT-6, (*b*) collection and shipment of laboratory specimens (or by laboratory) and notice to vaccine evaluation center, form FT-9, and (*c*) notification of physical therapist; (4) first muscle evaluation by physical therapist (10 to 20 days) and physician's interpretation of patient's status, form FT-7; (5) collection of convalescent serum for laboratory, form FT-9; (6) second muscle evaluation by physical therapist (50 to 70 days) and physician's interpretation of patient's entire illness, form FT-8; (7) report of virus isolation, tests of antibody titer, laboratory diagnosis, form FT-10; (8) establishment and application of criteria for diagnosis of individual patient; and (9) integration of all data into final vaccine evaluation center diagnosis.

The criteria for diagnosis of poliomyelitis, for designation of a case as paralytic and its severity, and for the interpretation of laboratory results were carefully drawn. In this we had the continued help of an advisory committee comprised of expert clinicians, virologists, biostatisticians, epidemiologists, and administrators. The information concerning each case was carefully reviewed and the diagnostic classification made without knowledge of its vaccination status so that objectivity was readily maintained. Inevitably, difficulties in decision were encountered when results from different pieces of data were not in agreement, but the effort was made to follow a consistent plan of interpretation.

RESULTS

The study period was defined as the period from two weeks after the time of the third injections in an area to Dec. 31, 1954. The beginning was selected because it coincided generally with the time when second blood specimens were obtained for measurement of antigenic response to vaccine. During the study period there were 1,013 cases reported to be poliomyelitis or suspected poliomyelitis; 428 in the total study population of placebo areas and 585 in the total study population of observed areas. With the criteria employed, 67.6% were classified as paralytic, 17.6% as nonparalytic, and 14.8% as not poliomyelitis or doubtful. There was no major difference in distribution of diagnoses in the two populations.

Table 3 shows the cases distributed according to the various segments of the total populations involved. It must be emphasized again that the evaluation is limited to a comparison of incidence *in the vaccinated* and in the established controls. The nonparticipating portions of the populations, that is, those who specifically refused to participate, are not additional controls. That decision was firmly established well in advance of the tabulation of results. The data are presented only because they are available and for completeness of reporting. The cases and rates per 100,000 of specific population are listed. In the placebo control areas there was a total of 82 cases reported among the 200,745 vaccinated and 162 among the 201,229 who received a placebo. The corresponding rates are 41 and 81—a ratio of 1:2; however, 25 and 20 cases, respectively, were classified as not poliomyelitis or doubtful. Thus, when the cases accepted as poliomyelitis are compared, there are 57 and 142, respectively, with rates of 28 and 71, a ratio of 1:2.5. When these are subdivided into paralytic and nonparalytic groups, no difference is observed between the incidence of nonparalytic cases among vaccinated and control persons. The sole significant difference, then, resides in the cases classified as paralytic poliomyelitis; there were 33 in the vaccinated group and 3.5 times as many, 115, in the placebo control group. In the observed control study, the number of controls is 3.3 times that of the inoculated; hence, for comparison the rates must be used. Here, again, there is no significant difference between the rates in nonparalytic cases or between the doubtful and not poliomyelitis groups in the vaccinated and control patients. The rates for paralytic cases are, however, 17 and 46 respectively —a ratio of 1:2.7.

This possibility was an essential reason for establishing the strictly controlled placebo study. Moreover, the uninoculated—or refused—portion of the second grade in observed areas also had a lower rate than the designated controls who themselves were both "yes" and "no" participants. When the incidence rates in control and uninoculated groups combined are calculated for the placebo study and for the observed study, they are the same: 43.7 and 43.9 respectively. The differences disappear.

Lack of Evidence of Provocation or Infection from Vaccination.—It had been suggested that the placebo inoculations might exert some provocative influence toward paralytic poliomyelitis. Analysis of the data reveals no evidence of exaggerated incidence or localization of paralysis associated with inoculations. Further information is presented regarding the occurrence of poliomyelitis in the total study populations during the nine-week period from the beginning of vaccination *to four* weeks after the third injections in an area. There were 129 reported cases. As seen in tables 4 and 5, *no distinctive difference* in incidence in time of occurrence of cases appears in the vaccinated, placebo, or uninoculated groups of the placebo areas, or in the corresponding groups of the observed areas. The latter included many more southern states where poliomyelitis was already being reported at the time of vaccination, especially in Texas where half of the cases occurred (tab

* Date of first inoculation in school used for uninoculated children. † Partial placebo, one case. ‡ Doubtful facial.

The lack of effect in nonparalytic cases may indicate that they include a sizable proportion of cases that in reality are not poliomyelitis or that vaccination did not prevent infection and minor degree of illness, although limiting the development of paralytic involvement. But it must also be pointed out that, with the criteria employed, only 15 to 17% of the cases remained in the nonparalytic category. The question has been asked why the incidence of paralytic cases is less in the uninoculated members of the population than in the placebo controls. One can only repeat that the populations receiving vaccine or placebo are strictly comparable in every characteristic; they are equal parts of one population, while those who refused participation are distinctly different.

. The number of cases in the first and third grade con- ıls and in the vaccinated group is directly propor- nate to the population. The tables also contain the ults of efforts to isolate virus from the reported cases. om the four cases of paralytic poliomyelitis among ›se receiving vaccine, partial or complete series, type 1 ·us was recovered once; the others were negative. ıliomyelitis virus was recovered only once from vac- ıated persons in the observed areas, a type 2. From lf of the paralytic cases in the control group in which ›sts were done, poliomyelitis virus was isolated: eight ʼpe 1 and four type 3.

There were only two instances of poliomyelitis in asso- iates of vaccinated persons during this nine-week pe- ʼod. The study member in New York state received the ıird injection of vaccine on June 17; the sibling de- eloped nonparalytic poliomyelitis 26 days later, and 2 ays later the vaccinated child developed poliomyelitis ʼith minimal paralytic signs; no virus was recovered. In ʼexas, a child received his third injection of vaccine on une 15, and 21 days later had the onset of mild bulbar ›oliomyelitis, but no virus was recovered. The sibling ıad his onset on the same day, with nonparalytic poliomyelitis and negative virus studies. There were three instances of similar nature in the placebo group, three in the uninoculated of the placebo study areas, three in the controls, and one in the nonparticipating group of observed areas. There is, therefore, no indication of undue transmission of poliomyelitis virus from vaccinated persons in this period to other members of the household.

Distribution of Paralytic and Laboratory Confirmed Cases.—The subsequent analyses of case distribution were directed toward the combining of clinical and laboratory data that enhance the reliability of diagnosis. A summary of these progessive stages with accompanying estimates of effectiveness in the two types of study are given in table 7. In the placebo areas there was a distinct trend for the differences in ratio between vaccinated and controls to increase as the severity of paralytic involvement increased. In spinal paralytic cases of minimal degrees of involvement the difference was only 2:1, suggesting that here, too, cases that were not specific poliomyelitis virus infections were included in these clinical classifications. In the more severe classes, however, the distinction became quite marked, emphasizing the possibility that the vaccine exhibited its major influence in preventing significant muscular impairment. The difference in rates for bulbospinal cases was pronounced and highly significant.

The same trend occurs among spinal paralytic cases in observed areas, but the difference between total bulbospinal rates is less, apparently owing to the lack of effect in cases with minimal paralytic ratings. The limited number of cases, however, can significantly limit the degree of numerical agreement in the two studies. Analysis of paralytic cases that were designated by virus isolation, serology, or virus in family associates as specific infections with the known types of poliomyelitis virus was then undertaken. This obviously reduces again the number of cases admitted to consideration. It is seen, however, that with these criteria, the estimated effect of vaccine was the same in spinal paralytic cases of both placebo and observed study areas. However, the discrepancy between the bulbospinal cases in the two studies persists.

TABLE 7.—*Estimates of Effectiveness of Vaccine at Successive Stages of Analysis*

* Because of small numbers the bulbar and fatal cases are omitted. All fatal cases occurred in controls.
† The difference in distribution of nonparalytic cases is not significant at any stage of analysis.
‡ Francis and others.[1]

Finally, the distribution was studied of all cases, paralytic and nonparalytic, from whom a specific poliomyelitis virus was isolated. In placebo areas an effectiveness of 68% was estimated against type 1, and 90% or more against types 2 and 3. In observed areas the trend was the same but lower. What, then, can be given as the effectiveness of vaccine? The calculations presented in the table appear to be valid estimates from the summarized data. Subsequent review has not revealed significant error. It is fully recognized that larger numbers would have created greater security, but the data obtained are unprejudiced appraisals. The strictly controlled placebo study provides the data in which there is greater confidence than those from the observed control study. In fact, the results from the observed areas would be more difficult to interpret if they had not followed the trend of those obtained in the placebo study. The lesser effect seen against type 1 virus is in accord with the lesser antigenic effect of a number of the preparations of vaccine measured against type 1 virus. But taking the composite results against laboratory confirmed cases of paralytic poliomyelitis an effectiveness of 80 to 90% was observed in the placebo study areas and 60 to 80% in observed study areas. It must be emphasized that the results presented apply to the circumstances in effect for the 1954 studies during which intensive efforts were made to obtain as complete and uniform data as conditions of study would permit.

There are questions arising from the data to which there is yet no ready answer. The incidence of paralyti cases in the 6-year-old group did not appear significantl different in vaccinated and controls of the placebo areas It can only be pointed out at the present that when thes cases were considered in terms of virus isolation, ther were four cases of type 1 in each group, but there wer no type 2 or type 3 cases in the vaccinated while one an five cases, respectively, occurred in the controls. Study this problem is continuing.

SUMMARY

This review has been directed to a further summar of the report of the evaluation of the 1954 field trial poliomyelitis vaccine. The data appear on further exar ination to retain their validity. Possible harmful effe of the poliomyelitis vaccine were not indicated by data. Again, the definition of controls and the value strictly controlled studies is emphasized. It is appare that the medical profession at large needs further pre aration for effective participation in the investigation health problems in which their activities as physicia may contribute the essential data.

The Care of Cardiac Patients.—*The pitfalls in the care* cardiacs are numerous, but mainly concern the original diagno of the case. Before a physician embarks on the treatment a given patient with heart disease he must ask *himself th* questions: *First, is organic heart disease present? Second, there evidence of congestive failure or coronary failure? Final* is there something peculiar about the problem that requi more than the ordinary type of treatment, *such as some fo* of surgical *operation (pericardial resection),* or is it a reversi form of heart disease, such as beriberi or thyrotoxic heart d ease? Only after these three questions are satisfactorily answer should the patient be placed on the customary program digitalis, diuretics, etc. When ordinary congestive heart failu is present, and the physician is certain that it is not due to o of the causes amenable to or curable by surgery, the proble is generally well treated by *the average* physician.—S. A. Levin M.D., Pitfalls in the Care of Cardiacs, *Annals of Internal Me cine,* June, 1955.

CONTROL OF POLIOMYELITIS THROUGH VACCINATION

Leonard A. Scheele, M.D., Washington, D. C.

ecent progress in poliomyelitis research has cul- ited, after a decade of work, in the development of ful vaccine[1] to combat paralysis. The vaccine is the and currently the only, control measure usable on ge scale that appears to provide substantial immu- against the paralytic form of this disease. Poliomye- is a nationwide health problem that has increased in and significance in recent years. It is one of the few municable diseases, in fact, that has shown a rise in incidence and death rates in the United States dur- he past two decades. Nonetheless, the incidence of cal poliomyelitis today is considerably less than that any other infectious diseases.

1954, the third highest year of reported poliomye- incidence in United States history, 38,741 cases of myelitis (including both paralytic and nonparalytic) were reported to the Public Health Service. In the year there were about 50,000 reported cases of in- ous hepatitis, 61,000 reported cases of whooping h, 145,000 reported cases of streptococcic sore at and scarlet fever, and 683,000 reported cases of les. It must be remembered, however, that the ulative total of individuals with residual paralysis poliomyelitis mounts each year. About 75% of all of poliomyelitis in 1954 occurred in children 1 to ears of age, with peak incidence, for the country as ole, among children 5 to 9. The age-specific inci- e varies according to geographical area, however, in recent years a definite shift to peak incidence in r children and adults has been observed in some of the country. In terms of morbidity and mortality, myelitis ranks well below most diseases of child- l. It is, however, a significant public health problem use of: (*a*) its seasonal and epidemic nature, (*b*) sidual and permanent disabling effects, (*c*) the fear dread it inspires in parents, and (*d*) the absence, now, of effective control measures.

fection with poliomyelitis virus is characterized by tiplication of virus in tissues of the gastrointestinal t, with resultant shedding of virus in pharyngeal se- ions and feces. At some stage in this infection there be a transient viremia. In a small proportion of s, the central nervous system may be invaded during viremia. Classic symptoms of paralysis, therefore, de- p only in a small proportion of the infections. Anti- l immune bodies that result from natural infection or n vaccination do not prevent subsequent infection of gastrointestinal tract but act as a barrier during mia to block invasion of the nervous system.

o practical measures for controlling the spread of omyelitis infection from person to person are known, the poliomyelitis vaccine has been demonstrated to effective in preventing the paralytic form of the dis- . Gamma globulin, when used prior to the viremic e of the disease, offers some short-lived protective ct by passive transfer of antibodies. Since the ratio of gnized cases to subclinical infections frequently ap- ximates 1 to 100,[2] infection is widespread early in the course of poliomyelitis outbreaks. Thus, gamma globulin cannot be administered to the personal associates of persons with the disease in sufficient time to prevent the disease. Community-wide use of this material has not been shown to produce substantial benefits.[3] Gamma globulin is therefore of little practical value in the mass control of poliomyelitis. It does, however, have value in individual instances when given before exposure to virus.

SALK VACCINE

Salk succeeded in developing a vaccine in which there is virus inactivation by chemical means. The Salk vaccine is an aqueous suspension of inactivated poliomyelitis virus prepared from a selected strain of each of the three virus types grown on monkey kidney cells. The formaldehyde inactivation is designed to render the virus harmless, while preserving its capacity to induce production of antibodies.

To be suitable for widespread application, a preventive agent should meet the following criteria: 1. It must be safe; that is, there must be assurance that it will not produce or provoke disease and that untoward or undesirable reactions will be negligible. 2. It must be effective. It must either prevent the occurrence of the disease or modify its severity to an appreciable degree. 3. The method of administration must be practical of application in private and in public health practice. The available evidence indicates that the Salk vaccine meets each of these criteria. This evidence comes from studies conducted by Salk, from tests of pharmaceutical laboratories, and from a large-scale field trial carried out during the spring and summer of 1954 under the sponsorship of the National Foundation for Infantile Paralysis. The field trial was a controlled study in which about 450,000 children, 6 to 9 years of age, in 44 states, received the vaccine. An additional 200,000 children were injected with a placebo material, and 725,000 children represented uninjected, observed controls. Thomas Francis Jr., of the University of Michigan, who was in charge of the evaluation, presented a comprehensive analysis of the results on April 12, 1955.[4] The report indicated that the vaccine had been safe and effective in substantially reducing the risk of paralytic poliomyelitis

in the vaccinated groups. The gross calculated degree of protection ranged from 60 to 90%; 60 to 70% effectiveness was found against disease caused by type 1 virus, the most prevalent type in cases of paralysis, and 90% or more effectiveness against that caused by type 2 and type 3 virus.

After its effectiveness was demonstrated in the field trial, the vaccine was licensed on April 12 for general use this year. Under sponsorship of the National Foundation for Infantile Paralysis, a large-scale immunization program was begun the second week in April among first and second grade school children. On April 12, Salk described a dosage schedule,[5] based upon antibody response studies, of three injections of 1 cc. each, to be given intramuscularly. The first and second injections are separated by an interval of two to six weeks and the third follows in approximately seven months. This differs from the schedule used in the field trial, when all three injections were given within a period of five to six weeks, only in the spacing of injections. Salk has presented evidence that the second injection is beneficial even if given after a number of months, and that giving the third injection about seven months after the first should induce a better antibody response than giving it earlier. In general, the revised schedule described by Salk was adopted for use in the vaccination program for first and second grade children sponsored by the National Foundation for Infantile Paralysis. The inadequate supply of vaccine has led to delay, in most instances, in giving the second injection.

DISTRIBUTION METHODS

The short supply of vaccine led to consideration in May of distribution methods and the establishment of age group priorities.[6] Under a voluntary plan of allocation and distribution, with age priorities based on risk of attack, the vaccine will be made available first to the children at greatest risk. For the country as a whole, the highest attack rates occur among children 5 to 9 years of age. The National Advisory Committee on Poliomyelitis Vaccine, which was established by the Secretary of the Department of Health, Education, and Welfare to study this problem, therefore recommended that this age group receive first priority. The committee has further recommended that, as vaccine becomes available, the existing priority group be broadened by adding, in equal proportions, children below 5 and above 9 years of age.

Medical organizations have agreed to follow a
tary control plan under which physicians will vacc
persons only within the priority groups. This place
sponsibility on the individual physician, with re
both to the use of the vaccine and to the education o
patients to accept use only in the priority age groups

PROVOCATION

The possibility that the phenomenon of provoca
might be involved in the injection of vaccine during
riods of high incidence or epidemics has aroused c
siderable discussion among physicians and scientis
On June 18, the National Foundation for Infantile Par
ysis convened its Vaccine Advisory Committee, rep
sentatives of certain professional groups, and spec
consultants, to consider this problem. The organizatio
represented included the American Academy of Pe
atrics, the Academy of General Practice, the Americ
Medical Association, the American Public Health As
ciation, the Association of State and Territorial Hea
Officers, and the U. S. Public Health Service. The gro
agreed unanimously [8] that "the total preventive effect
the vaccine in a period of rising poliomyelitis incide
should be much greater than the possible hazard fr
the provoking effect of the injection. Those present a
concluded that the benefit to be gained by poliomye
immunization, in contrast to the small potential risk
provocation, increases in proportion to the severity
the poliomyelitis incidence, since a larger number
paralytic cases should be prevented during the en
period of the epidemic."

This general recommendation was based on infor
tion available at this time. Specifically, the vaccine is
pected to produce some antibody within a week to
days after the first injection, and even small amount
antibody may have some effect in preventing paral
poliomyelitis. Therefore, "the onset of antibody resp
to the vaccine may eliminate any subsequent provo
effect of the vaccine injections." The evidence for
includes experience with the use of gamma glob
during a 1952 epidemic in Sioux City, Iowa,[9] exp
ments on development of immunity in monkeys,[10]
observations on the occurrence of poliomyelitis in
southern states during the 1954 vaccine field trial.

Contraindications to the use of vaccine during
riods of high incidence cited by the group [8] were:
symptoms of minor illness, especially fever, sore thr
or gastrointestinal upset at the time of the proposed
jection; and (2) occurrence of a case of poliomyeliti
the household immediately preceding the proposed
jection. It is known that almost all the other mem
of the household are already infected when paralysis
appears, so that vaccine cannot be expected to pro
against an already existing infection, and an injectio
that time might provoke paralysis in the course of
otherwise inapparent infection.

SAFETY OF VACCINE

The question of safety of the Salk vaccine has a
been the subject of considerable public and professio
discussion. During the vaccine's development, field tr
and initial use, many problems arose, which were de
with through close cooperation between Salk, the ma

cturers, and the Laboratory of Biologics Control of the ublic Health Service. The experience that had been ined by April 12, 1955, established confidence in the fety of the experimentally produced vaccine and pro- ded the basis for requirements designed to assure fety, purity, and potency.

The value of the vaccine as demonstrated in the 1954 ld trial, plus the over-all experience and competence the firms producing the vaccine and the participation the Laboratory of Biologics Control in the field trial sting and subsequent developments, led to prompt censing of the six pharmaceutical manufacturers whose plications were pending. Most of the lots of poliomye- tis vaccine were released on review of protocols, i. e., e manufacturer's detailed reports on manufacture and sting of each lot.

The occurrence of poliomyelitis among children re- eiving vaccine from the Cutter Laboratories led the ublic Health Service to request this manufacturer to ithdraw its product, and the company complied im- ediately. A thorough investigation of the plant and its anufacturing processes was instituted. Extensive labo- atory tests of the material and field observations of the ccurrence of all poliomyelitis cases were begun. Shortly ereafter, the in-plant study was extended to other embers of the industry in order to determine whether here were common problems relating to production ethods and to the adequacy of the testing requirements. This led to a temporary suspension of the nationwide accination program.

The investigation indicated that the records that the manufacturers had been required to submit did not bring out certain important data on processing and testing. Manufacturing experience revealed that inactivation of virus in the production of vaccine did not always follow the predicted course, inasmuch as infective virus was sometimes detected after the expected completion of inactivation. This meant that greater dependence must be placed as an integral part of process control, on tissue culture testing of larger volumes of vaccine to detect small quantities of residual live virus.

Changes incorporating this new knowledge were made in processing control and safety testing. New principles of testing were added to the Minimum Requirements for the production of poliomyelitis vaccine.[11] These principles should result in a product essentially free of live virus. On the basis of probability computations, a liter of the vaccine made under the amended requirements should contain 5 or more live virus particulates less than once in 100,000 times (see this issue, page 1249). Risk of transmission of poliomyelitis through use of such vaccine is negligible. Remember, however, that 100% safety cannot be assured for the poliomyelitis vaccine, just as it cannot be assured for other biologicals used in preventive and therapeutic medicine.

NEED FOR CONTINUING STUDY

It has been obvious from the time of the field trial that the vaccine needs further study and observation. Precise knowledge of the vaccine is limited to the experience and data gained as a result of that trial. The effectiveness of the vaccine has not yet been studied in age groups other than those observed in 1954. Research and additional experience with application of the vaccine should enable us to fill many gaps in our knowledge. It must be remembered that the need for continuing study of poliomyelitis in general and of this vaccine in particular is no different than the need for continuing study of other diseases and of the preventive and therapeutic agents.

The field trial provided no data on the effectiveness of the vaccine in children under 6 or over 9 years of age. The data indicated, in fact, that the greatest amount of protection occurred among children 9 years of age and that the degree of protection decreased progressively with age. Although Salk has presented data showing that children under 6 developed antibodies after injection, the relationship between antibody development and protection against paralytic poliomyelitis in these younger children is still under study. There is, therefore, need for additional information and for careful evaluation of the vaccine's effectiveness in both older and younger children. The answers can come only if large numbers of children are vaccinated and observed.

Optimum dose and interval between injections represent other problems needing additional study. Here again firm knowledge is limited to the field trial experience. The effectiveness of the vaccine under the modified dosage schedules that have been recommended for use this year remains to be determined. The question of duration of protection and the best timing of "booster" shots cannot be answered at this time. It is not yet known whether additional injections will be needed at stated and frequent intervals or whether the first series will provide protection for an extended period of time. Salk has observed detectable levels of antibody for 28 to 30 months after vaccination (see this issue, page 1239).

Additional research is also going forward on safety of the vaccine. The Mahoney virus strain, a strain of type 1 virus that is highly antigenic but is also highly invasive, is now employed in the vaccine. In order to provide an additional margin of safety, there is general agreement that a type 1 strain that has satisfactory antigenic properties but that is less invasive should be sought, with a view to substituting it in the vaccine. Several laboratories are now working on this problem. Other problems related to virus vaccines and the control of poliomyelitis will be under study. Among these are the combination of the Salk vaccine with other prophylactic agents, just as diphtheria and tetanus toxoids are now administered together, and the development of vaccines based on different principles than those employed in the Salk process.

Although we can expect further research and observation to lead to improvements, the vaccine is, at present, our most useful weapon in the prevention of paralytic poliomyelitis. Its development has opened the way for new achievements in poliomyelitis control. This medical discovery, like others in the past, brings new opportunities in preventive medicine to the practicing physician and the public health worker.

---

[11] Technical Report on Salk Poliomyelitis Vaccine, Public Health Service, Department of Health, Education and Welfare, June, 1955.

DISCUSSION OF PANEL ON PROSPECTS FOR CONTROL OF POLIOMYELITIS

Dr. Albert Sabin, *Cincinnati:* With full appreciation for the important recent advances in our knowledge of immunization against poliomyelitis, it may nevertheless be said that the prospects for the control of poliomyelitis depend more on what still remains to be learned than on what has been learned thus far. Salk has demonstrated that a sufficiently potent, formalinized vaccine can be prepared in the laboratory to produce antibody in children who had none to begin with, and the extensive field trial of 1954 has provided evidence that the incidence of paralytic poliomyelitis in school children can be significantly reduced even by vaccines that are not of optimal potency. The important questions now before us are concerned with the quantitative aspects of the safety and effectiveness of such vaccines produced on a mass scale for mass use in human beings of all ages. The most recent experience has shown that it is possible to prepare many large lots of formalinized vaccine that can be administered to millions of children with impunity. On the other hand, the circumstances surrounding the serious epidemic of type 1 paralytic poliomyelitis that has followed the use of two large lots of mass-produced vaccine indicate that the originally prescribed safety tests do not with regularity detect minimal amounts of virus that can become a source of considerable danger. This is due to the fact that at least one of the components of the vaccine, the type 1 virus, is the most virulent strain studied thus far. More recently material produced by another company has come under suspicion because of the occurrence of a small but disproportionately unexpected number of paralytic cases, in some of which there was initial paralysis in the inoculated extremity. It is possible that the more stringent safety tests that were recently recommended by the U. S. Public Health Service may avoid such accidents in the future, but the effectiveness of these new procedures has not yet been established by tests on the lots of vaccine that have proved dangerous in recent weeks. Children without antibody may be as susceptible to minute amounts of fully virulent virus as any tissue culture bottle or monkey. Therefore, 100,000 children may still be better indicators of minute amounts of virus that have not been inactivated than the smaller numbers of tissue culture bottles and monkeys that can be used practically in the most rigid safety tests. Accordingly, it would seem to me highly desirable to replace the virulent viruses currently used in the preparation of formalinized vaccine by experimentally segregated or naturally occurring antigenically potent strains that are dominantly avirulent for monkeys by both the intracerebral and the intramuscular routes. While a single tissue culture dose of the virulent type 1, Mahoney virus can produce paralysis in intramuscularly inoculated monkeys, 10 million tissue culture doses of the avirulent variants can be inoculated without producing paralysis. We now have such strains for each of the three types, and their antigenic potency after formalinization is now being investigated in Sweden and in England by the quantitative method of assay in guinea pigs developed by Dr. Sven Gard and his associates.

The antigenic potency of mass-produced formalinized vaccines must be carefully controlled by an adequate, quantitative method of assay if the expected protection is to result from their use. Salk's standard reference vaccine even in one dose seems to produce antibody more regularly than the three doses of most vaccines used in the 1954 field trial. Whether the various factors responsible for deterioration of antigenic potency in the 1954 vaccines have now been overcome and whether the current trend for more prolonged "cooking" with formaldehyde solution (Formalin) in an attempt to achieve a greater margin of safety might affect antigenic potency—these are both questions that cannot now be answered, because the estimates of potency currently in use in this country either are not sufficiently quantitative or are unrelated to human response. Studies recently completed and communicated to me by Dr. Sven Gard in Sweden indicate that the guinea pig method of assay yields quantitative data similar to those obtained in children without antibody and should therefore become a useful tool for safeguarding the potency of formalinized poliomyelitis vaccines. If one can be assured of getting mass-produced vaccines as good or nearly as good as Salk's standard reference vaccine, one might look forward to better results than were obtained in the 1954 field trial, when th effect decreased progressively in younger age groups t a point where the protection afforded 6-year-old childre was not regarded as statistically significant.

And how long will the protective effect of the best fo malinized vaccine last? The only honest answer, course, is that we do not know. If not more than the cu rently proposed three doses are given, time will provid some sort of answer only if the poliomyelitis surveillan unit established by the Public Health Service during t recent emergency will continue its excellent work for long as it may be necessary to obtain an answer. Salk hypothesis that natural infection may itself provide t booster for an accelerated antibody response and th prevent paralysis is based on observations following i tramuscular injections of preformed antigen but is n supported by any data on the effect of feeding virus. M own observations on feeding attenuated viruses to vo unteers with barely detectable or minimal amounts antibody indicate that the antibody response in suc people is usually not accelerated.

Will widespread immunization of the younger a groups with formalinized vaccine interrupt the chain infection and thus eliminate the paralytic disease that i many countries with advanced standards of hygiene now such a serious problem in those persons who ar over 20 years of age? Again the honest answer is that w do not know, for alimentary infection in the presence c antibody may depend on the size of the infective dose, an this also must be investigated in greater detail in the fu ture. A recent serologic survey completed in my labora tory indicated that among eighty-three 21 to 30-year-ol Americans of the middle income groups 57% had n lemonstrable antibody for type 1 and 87% lacked antiody for one or another type of poliomyelitis virus. These eople also need protection against paralytic poliomyeitis, and if a vaccine provides only transitory immunity ve may well raise a highly susceptible adult population hat would be in great danger if a highly virulent polionyelitis virus were suddenly introduced in their midst rom the outside world.

Should we wait for years to find out what the best illed virus vaccine will do, or should we now increase our fforts to learn everything we can about the possibility of mitating the mechanisms by which natural infection mparts lifelong immunity? I think it would be poor stratgy to wait. The experiments carried out in my laboratory n experimentally segregated and naturally occurring atenuated poliomyelitis viruses of all three types, the reovery by Li and Schaeffer of an especially avirulent ype 1 strain derived from the Mahoney virus, and the xperiments of Koprowski and his associates with atenuated types 1 and 2 viruses all indicate that suitable trains are now available for pursuing this problem slowly nd cautiously but nevertheless vigorously.

My own studies on human volunteers have already ndicated that the ingestion of as little as 0.001 cc. of ulture fluid of any of the three types or simple swabbing f the throat with minute amounts of virus can induce ymptomless immunogenic infections. It is especially oteworthy that the attenuated viruses possess the sigificant characteristic of not producing viremia despite xtensive multiplication somewhere in the alimentary ract. Neither the original attenuated viruses nor the rogeny resulting from multiplication in the alimentary ract produce paralysis in chimpanzees after direct inculation of large doses into the gray matter of the spinal ord.

It would be fine if it should turn out that there were no eed for the practical application of the information acuired from careful studies on attenuated viruses, but it would be a pity not to have this knowledge in reserve if it should turn out that it were needed for the ultimate control of poliomyelitis on a world-wide basis. Let us not confuse the first great victory with total victory, and let us not disband too soon the great poliomyelitis army and general staff that has made the present advances possible. Finally, let us be guided by the words of Sir Francis Drake, who said: "Grant us to know that it is not the beginning, but the continuing of the same until it is thoroughly finished, which yieldeth the true glory."

DR. JOSEPH STOKES JR., Philadelphia: In discussion of poliomyelitis vaccination at this critical period following Dr. Francis' and Dr. Salk's most valuable reports of success in children with certain batches of vaccine; and following the later reports of infective batches of vaccine in the United States resulting in a crippled vaccination program; and finally when the season for the disease is upon us, it would not appear worthwhile in this panel to review the difficult problems of public relations. The primary question on every physician's mind here today, in fact in the entire country both among the medical profession and the lay public, is with respect to the safety of the vaccine and not with respect to its potency.

I had no opportunity to see these papers, except a considerable portion of Dr. Salk's, before this morning but have been impressed again with how easy it is to discuss increases in antibodies and how difficult it is to come to grips with the question of safety. It has been tempting when drawing a curve of inactivation of virus by formaldehyde solution (Formalin) to make it a straight line, showing complete inactivation of the virus within a few days. We have seen such a straight line this morning. To my knowledge laboratories working in this field, and I have talked to a considerable number in the last few days, all have agreed that the inactivation of the poliomyelitis viruses by formaldehyde solution, 1:4,000, in a majority of instances is not a straight line but a curve that varies at times up to the point of being almost asymptotic.

Since testing samples of vaccine for infective virus must be random at present, and if the curve of inactivation by formaldehyde solution, in a majority of instances, is not a straight line, then the infective particles may be missed in such sampling procedures. In this respect it would be extremely helpful if methods of concentration and purification of the virus were available for such testing for infective particles so that the sampling would afford more complete information. Such methods are now being made available. But at present there is no way of being completely certain that batches of vaccine are not infective. If the inactivation of virus is a curve in the majority of instances, then there may be a very narrow separation between a vaccine batch that is infective and a batch that no longer has potency for immunizing. It has been said that the infective batch or batches mentioned this morning were carefully reviewed with respect to their method of preparation and that no essential difference was found, except the method of preservation, between the preparation of these infective batches and other batches of vaccine. I believe this to an extent is the crux of the fear expressed concerning safety, in that no specific fault has been demonstrated that has separated the infective batches from others until Dr. Shannon's report this morning. It is fortunate that in Canada, where 700,000 doses of vaccine have been administered without evidence of infection, one laboratory has been responsible for the production of all of the vaccine, but, when the range between infectivity and potency may be very narrow, the necessary multiplication of laboratories for production would seem to enhance the dangers.

Also, I should appreciate some discussion from Dr. Salk of the possibility of reactivation of virus after standing when the formaldehyde has been neutralized, or of reactivation after injection. I am glad to hear him say that he feels the less virulent and yet antigenically active strains of type 1 should be used in preference to the highly virulent, but not so antigenically active, Mahoney strain used in the original trials.

It is important to remember that the reports we have heard are but one step, although a very important one, in the long road ahead toward the control of poliomyelitis. In considering this slow progress in such control I should like to ask three fairly simple questions: 1. Why not protect the central nervous system with passively transferred antibodies either administered parenterally or acquired transplacentally while the individual is exposed by the natural alimentary route to attenuated living virus that does not produce paralysis in monkey or man? 2. Would this procedure not involve a lesser risk than a possible escape of a few particles of living, but fully virulent, virus from formaldehyde-inactivated vaccine, which at times may not be inactivated, and which is administered by the unnatural parenteral route to the most susceptible species, man? 3. Why run the risk of precipitating paralysis of a limb by injection of any material other than antibodies in an individual who may be harboring virulent virus?

Five years ago, Koprowski, Jervis, and Norton, who originated the use of attenuated living virus, fed a group of young children live, attenuated type 2 poliomyelitis virus (the T N strain) in the form of cotton rat cord tissue. None of the children showed signs of illness or any untoward reaction following the oral administration of virus, and all developed homotypic antibodies in their blood. Subsequently, Koprowski, Jervis, and Norton demonstrated that the level of protective antibodies remained high during a four year observation period after the single feeding of modified live virus. In the course of the past three years, a type 1 strain of virus the S M strain) became attenuated and proved to be onpathogenic for laboratory primates when injected intracerebrally. This strain was then employed by these investigators for oral administration to a group of 15 children who had no poliomyelitis antibodies prior to feeding. The results were most encouraging, since all of the children who ingested virus developed homotypic antibodies, again without the slightest sign of illness.

In the course of these and more recent clinical trials conducted by Koprowski, Jervis, Norton, and myself, observations were made on the response of nonimmune individuals to the simultaneous feeding of types 1 and 2, as represented by the SM and TN strains respectively. Good antibody responses were obtained in 22 children who received gamma globulin immediately after being fed the SM strain of type 1 virus, thus indicating that the gamma globulin did not seem to affect the antigenic activity of the attenuated virus. Each of the 22 individuals developed antibodies with no sign of illness after becoming an intestinal virus carrier. Similar results have been obtained with the T N strain of type 2 virus.

I have mentioned these results to indicate a possible method of immunization that could presumably require no parenteral injections in infants and perhaps a single injection of gamma globulin in older children, while at the same time permitting the development of active immunization during the period of passive immunity afforded to infants by the mother, or in older children by the gamma globulin. Such a method is obviously in its earliest experimental trials, but the results already obtained fully warrant further active study.

QUESTIONS AND ANSWERS

The following questions were among those asked by the members of the audience at the Panel Discussion on Poliomyelitis held as part of the Annual Meeting of the American Medical Association, Atlantic City, June 7 1955. The answers to these questions were given an subsequently edited by the members of the panel unde the direction of the moderator, Dr. Van Riper; the questions have been grouped together under various headings.—ED.

Vaccine Preparation and Storage

QUESTION: How long does it take to prepare each l of vaccine if it passes each test satisfactorily? What i the shortest number of days?

ANSWER: A total of 120 days is required to complet the processing from virus culture to final testing of th packaged vaccine.

QUESTION: What antigenicity tests are done on th various lots of various producers to assure uniform lo of vaccine?

ANSWER: The antigenicity tests done on the variou lots of vaccine to assure uniformity are made by vaccinating groups of 12 monkeys and testing the seru antibody level against each of three types after a standard schedule of immunization. For this purpose thre doses a week apart are administered and blood draw one week after the third dose. The level of antibody induced by the unknown vaccine is compared with th induced by a standard preparation referred to as reference vaccine "A." The geometric mean level of antibod induced by the test vaccine must be equal to or great than a certain level as compared with reference vacci "A." A vaccine that fails to pass such tests for all thre types is considered unsatisfactory for use.—JONAS SALK, M.D.

QUESTION: For inactivation are these the total processes used: Formalin, heat, dilution, and usual steri processes of manufacture?

ANSWER: The virus fluid is filtered, formaldehy solution (Formalin) is added to it in concentration 1:4,000 and it is then incubated at 37 C until all vir particles have been inactivated.

QUESTION: Do the present vaccines lose their poten with age? Do you recommend refrigeration storage the vaccine?

ANSWER: The vaccine, under present standards, ha a six month expiration date. It should be stored unde refrigeration at a temperature between 35 and 50 F, th lower limit being preferred. Freezing should be avoide

QUESTION: Could you relate the names Brunhilde Lansing, and Leon to virus type (either 1, 2, or 3) an to the names Mahoney, MEF, and Saukett now bein used?

ANSWER: Brunhilde and Mahoney are strains of typ 1, Lansing and MEF-1 strains of type 2, and Leon an Saukett strains of type 3 virus.

Safety Tests

QUESTION: What safety tests are now used: bacteriological, monkey inoculation, other animals, tissue culture? Are these tests done on all lots?

ANSWER: Prior to inactivation each virus pool is tested for the presence of B virus and Mycobacterium tuberculosis. After inactivation each monovalent strain pool is tested for infectious virus by tissue culture methods. Each lot of trivalent vaccine is tested for infectious virus by tissue culture methods. The final vaccine pool is tested for lymphocytic choriomeningitis virus in mice inoculated intracerebrally. The final vaccine pool is tested for residual active poliomyelitis virus by intracerebral inoculations into 12 rhesus or cynomolgus monkeys and intramuscular inoculations into 6 cynomolgus monkeys.

QUESTION: Is it clear that after the new safety measures outlined by Dr. Shannon the vaccine will still be as potent as the vaccines used in the field trial?

ANSWER: The added safety testing does not in any manner affect the potency of the vaccine.

QUESTION: Does vaccine now in hands of state and school health departments meet new safety standards for resumption of inoculation programs? So far as we know these lots have not been recalled and retested.

ANSWER: All lots of vaccine in the hands of public health departments meet the revised standards for production and testing. All lots not meeting these requirements have been recalled by the manufacturer.

QUESTION: 1. Was each lot of vaccine used in 1954 approved by the manufacturer, by Dr. Salk's laboratory, and by the National Institutes of Health before release? 2. Was the same procedure followed for all vaccine in 1955? If not, please give details.

ANSWER: 1. Yes. 2. The licensed vaccine released by the surgeon general of the U. S. Public Health Service for use in 1955 was tested for safety, potency, and sterility by the manufacturer. In some instances complete or total testing for safety, potency, and sterility was carried out by the National Institutes of Health.

QUESTION: Are the controls of vaccine made at Connaught Laboratory in Canada similar to the United States controls? The program was continued in Canada.

ANSWER: The vaccine produced by the Connaught Laboratories in Toronto, Canada, for use by the Canadian Provincial Health Departments, was made in the same way in which the vaccine was produced in the United States. The Connaught Laboratories tested the vaccine for safety, potency, and sterility and concurrently the product was tested by the Dominion Laboratories in Ottawa. The program was continued in Canada with approximately one million children receiving two doses of vaccine, without the development of a single case of associated paralysis.

QUESTION: Were tissue culture tests (in various concentrations) used in 1954 vaccine?

ANSWER: In 1954 the vaccine was tested for presence of viable virus both in tissue cultures and by monkey inoculation.

Vaccine Dosage and Schedule of Administration

QUESTION: What is now considered to be the ideal interval between the three injections?

ANSWER: The present recommended schedule for vaccine administration is: (1) 1 cc. of vaccine injected intramuscularly; (2) 1 cc. of vaccine injected intramuscularly two to four weeks following the first injection; and (3) a booster shot of 1 cc. injected intramuscularly not sooner than seven months after the second dose and prior to the onset of the next epidemic season.

QUESTION: How long after the first injection can the second one be given and still produce what would be considered an effective immunization?

ANSWER: It has been reported that the sensitization of the individual that results from the first injection of vaccine is not lost if the second dose is delayed for as long as six months to a year; however, optimal protection cannot be anticipated until the complete series of three injections has been given. Dr. Salk has indicated that total antibody response is in direct proportion to the total mass of the antigen.

QUESTION: Is it advisable to administer the second dose of poliomyelitis vaccine as late as two months after the first dose? Our first injections were given April 25, 26, 27, 1955 in Memphis, Tenn. Vacation period began June 3, 1955.

ANSWER: The second dose of vaccine should be given as soon as the vaccine is available provided a period of at least two weeks has elapsed since the first injection.

QUESTION: First doses of vaccine were given many weeks ago. A long delay has ensued. Shall we now ignore the first dose and begin with a new first dose?

ANSWER: The effect of the first dose of vaccine is not lost if the second dose follows the first within a 12 month period.

QUESTION: How would 2 cc. of vaccine given affect (1) immunity response and (2) undesirable reactions?

ANSWER: 1. The use of 2 cc. of vaccine as the primary sensitizing mass would probably not be any more effective than 1 cc. 2. Many instances are reported of children having received 2 cc. of the vaccine without reaction.

QUESTION: Because of three types of virus, it is advisable to vaccinate previously infected children and adults?

ANSWER: Yes. Paralytic consequences of poliomyelitis infection give immunity only to the virus of the type that caused the paralytic infection. The individual remains susceptible to paralytic infection by the other two types until complete immunity is attained to all three types.

QUESTION: In light of the fact that the Salk vaccine is a pooled three-virus vaccine, what would you advise concerning vaccination in the case of 9-year-old child who last summer had poliomyelitis affecting the right side of the body? Should one give the pooled vaccine or only use the two viruses in separate vaccination to immunize against bulbar involvement?

ANSWER: All three types of virus may produce the same paralytic consequences. Until a simple, readily available test for immunity is developed, an individual who has already suffered a paralytic attack of poliomyelitis should receive the trivalent vaccine.

Clinical Questions

QUESTION: Does the poliomyelitis vaccine protect against the whole disease (such as enteric manifestations) or does it simply prevent the paralytic form?

ANSWER: The vaccine does not protect the individual from subsequent enteric infection; where effective the vaccine only protects aginst the paralytic consequences of systemic infection.

QUESTION: Does the Salk vaccine have any use in treatment of poliomyelitis?

ANSWER: No.

QUESTION: If poliomyelitis does develop in spite of injection with the Salk vaccine, is the clinical picture and symptom pattern the same as the usual picture of polioyelitis or is there any alteration or modification of mptoms?

ANSWER: An individual incompletely immunized may present clinical symptoms similar to those seen in a vaccinated person. The Francis report suggested that, where clinical infection occurred in spite of vaccination, it was less severe.

QUESTION: Should we postpone tonsillectomies until the end of the poliomyelitis season because of the danger of precipitating bulbar poliomyelitis in children or in close contacts of children who have been inoculated with Salk vaccine produced under the old standards for safety in which there is no certainty that all the virus in the vaccine is actually killed?

ANSWER: Elective tonsillectomies should be postponed when cases of poliomyelitis are being reported in the community. This practice should be continued until there is further evidence as to the effectiveness of the immunization that results from the use of the Salk vaccine.

Contraindications

QUESTION: Please list specific contraindications to poliomyelitis immunization. What of immunization to children recently ill with repeated upper respiratory infections?

ANSWER: The same contraindications to use of poliomyelitis vaccine should be observed as in the use of other comparable biologicals. Vaccination should be delayed where an individual has had known contact with a paralytic poliomyelitis infection, either in the home or among close intimate contacts. A child who evidences illness should not receive the poliomyelitis vaccine.

QUESTION: Are there any contraindications to giving the poliomyelitis vaccine shortly after recovery from illnesses such as chicken pox, mumps, purulent meningitis, or acute encephalitis?

ANSWER: As soon as an individual is completely recovered from an infection such as chicken pox, mumps, purulent meningitis, or acute encephalitis, it should be perfectly safe to carry out a course of poliomyelitis vaccination.

QUESTION: Is there any contraindication to the giving of other vaccines (typhoid, tetanus toxoid) at the time of giving poliomyelitis vaccine?

ANSWER: There is no reason to believe that a multiple antigen may not be given, and eventually poliomyelitis vaccine may be given combined with other biologicals.

Reactions to Vaccine

QUESTION: What are the percentages, approximately, of reactions to the first inoculation of vaccine in school children in 1955?

ANSWER: Untoward reactions following the administration of properly inactivated poliomyelitis vaccine have been minimal. This matter was thoroughly explored and presented in the Francis report evaluating the 1954 field trial. No major reactions could be attributed to the vaccine. Minor reactions were as frequent among children who received placebo as among those who received vaccine; namely, 0.4%. Experience in the 1955 vaccination program has not been evaluated in the same way as data collected for the 1954 field trial evaluation; however, there is no reason to believe that the incidence of reactions to properly prepared vaccine was any higher in 1955 than in 1954.

QUESTION: Is there any possible danger of horse serum allergic reaction to the Salk vaccine?

ANSWER: There appears to be no danger of allergic reactions in persons sensitive to horse serum.

QUESTION: What authorities on Rh erythroblastosis have approved the safety of the poliomyelitis vaccine from the standpoint of Rh trouble? What are views of Levine and Wiener?

ANSWER: Wiener is on record as having stated that Rh-Hr sensitization would not result from the use of the Salk vaccine.

QUESTION: What are the possibilities of developing chronic glomerulonephritis with repeated use of the Salk vaccine?

ANSWER: Adequate follow-up on a number of individuals who have received repeated injections of the Salk vaccine fail to show the development of any evidence of kidney damage.

QUESTION: May allergy injections such as "cold vaccine" be given in close proximity (one week) to administration of poliomyelitis vaccine?

ANSWER: Yes.

Negative Phase

QUESTION: Has any investigative work been done or, not, will investigative work be done in the immediate uture to determine whether children who have titratable evels of poliomyelitis antibodies in their blood as a reult of either prior poliomyelitis infection or inoculation f poliomyelitis vaccine will after receiving an injection f poliomyelitis vaccine experience a negative phase rection, with marked drop in antibody titer during the rst 24 or more hours after inoculation, before the antiody titer rises to new high levels? If such a negative hase does occur, the giving of poliomyelitis vaccine durng poliomyelitis epidemic periods could pose a hazard o children who may already be immune and who harbor oliomyelitis virus in their intestinal tracts.

ANSWER: Studies have been done to determine whether or not a drop in antibody titer occurs after inculation, and if there is any change it has not been erceptible even in individuals with low levels of antiody.—JONAS E. SALK, M.D.

QUESTION: Is there any increased susceptibility to oliomyelitis infection immediately after first vaccine ose? In other words, is there a negative phase?

ANSWER: This question can be answered in terms of ntibody level wherein it is found that antibody level rises rather than declines after the first dose of vaccine. As for a single dose of vaccine increasing susceptibility, here are no theoretical reasons why this should be the ase. In experimental animals it has been shown that ntibody development and resistance to infection occur lmost simultaneously.—JONAS E. SALK, M.D.

Epidemiological Questions

QUESTION: 1. What are the chances statistically that n immunized child will develop poliomyelitis from the vaccine? 2. What are the chances that an immunized child will develop poliomyelitis in spite of the vaccine? 3. What are the chances that a nonimmunized child will develop poliomyelitis?

ANSWER: 1. None from properly inactivated vaccine. 2. The chances that an immunized child will develop poliomyelitis in spite of having been vaccinated vary with he virus type. The chance of developing type 1 poliomyelitis is approximately 30% and of type 2 or type 3 perhaps 10%. 3. A study by Kumm on the risk of conracting poliomyelitis concluded that among children born in Connecticut, Massachusetts, New York, and North Carolina in 1930, 1931, or 1932, one out of every 156 acquired poliomyelitis in the first 20 years of life. Variations in this figure could be expected in different localities.

QUESTION: Dr. Francis referred to those who did not participate in the field trials as a "different population." What is meant by saying that the rate of poliomyelitis in this group is irrelevant and, if so, why? What is meant by "a different population?"

ANSWER: It has long been suggested that studies based upon volunteer participation possess an inherent difficulty if those who refuse to volunteer are accepted as controls. A number of studies have also pointed out that antibodies and resistance to poliomyelitis are acquired later in populations of high economic status than in the lower economic groups. There were indications that volunteering for participation in the evaluation program might well be influenced by such factors and consequently that those who refused would present characteristics that would suggest that they were really a more resistant segment of the population immunologically. A survey, to which reference has been made, did in fact yield results indicative that the "no's" were a different population. The population receiving vaccine and placebo are parts of the same population that requested participation, apparently similar in every way. The difference in incidence between placebo and uninoculated groups was thus anticipated. The uninoculated who refused inoculation are not part of the study.—THOMAS FRANCIS JR., M.D.

QUESTION: 1. Just what is meant by the vaccine being 60 to 90% effective? 2. Does it mean that in certain groups given the vaccine only 60 out of 100 showed protective antibodies?

ANSWER: 1. The effectiveness of the vaccine was measured by comparing the paralytic attack rate among those vaccinated with the rate observed among controls. Thus, if there are 60% less cases in the vaccinated than would be expected among the same children had they not been vaccinated, the vaccine is considered 60% effective. 2. No. Effectiveness was measured in terms of protection against paralytic disease, not by measuring presence or absence of antibodies.

QUESTION: 1. What is the hazard of giving vaccine in an epidemic season? 2. What is the hazard of giving a second dose?

ANSWER: 1. The hazard of giving vaccine in the epidemic season is less than the protection afforded by the vaccine. 2. Since the first dose of vaccine has already produced detectable antibody, though not enough to assure total protection, it is sufficient to eliminate any hazard in connection with the giving of the second dose of vaccine.

QUESTION: Instead of giving day-to-day reports on poliomyelitis vaccination or predicting by weeks and months, why not postpone start of immunization until fall months when possible poliomyelitis virus carriers will have diminished and possibility of activating a dormant virus will be less risky?

ANSWER: As soon as the supply of poliomyelitis vaccine is adequate to meet the demand, immunization will undoubtedly be carried out during the season of the year when poliomyelitis outbreaks are less likely to occur in each community.

Provoking Effect

Question: What is the danger of giving intramuscular injections of poliomyelitis vaccine during the summer to children who might be contact carriers of poliomyelitis?

Answer: At a meeting held in New York City on June 18, 1955, it was concluded that "provocation" was minimal in connection with intramuscular injection of poliomyelitis vaccine; that the probable protection from paralytic poliomyelitis as opposed to the provocation of paralysis was so much greater that continued use of vaccine was recommended during the epidemic season.

Question: Does the stick of the needle predispose to paralytic poliomyelitis if the patient has poliomyelitis virus in the gastrointestinal tract?

Answer: In the absence of viremia there is no evidence to support the belief that the mere puncturing of the skin would provoke an attack of paralytic poliomyelitis.

Question: What about any injection during the poliomyelitis season? Even a blood cell count?

Answer: In the presence of viremia any parenteral injection may result in the localization of paralysis in the extremity into which the injection is made. This is especially true where the precipitated biologicals are used, such as tetanus toxoid, diphtheria toxoid, or pertussis vaccine. There is no evidence to support the belief that the mere puncturing of the skin or taking a blood sample for a blood cell count would precipitate an attack of paralytic poliomyelitis.

Question: Is it safe to give poliomyelitis vaccine in the presence of an epidemic?

Answer: Yes—provided the individual has had no known contact with a paralytic case.

Question: How late in the summer should immunization be begun?

Answer: It is recommended that primary immunization be given at any time in the year, recognizing that if the individual is already harboring the virus of poliomyelitis the vaccine will not protect against the paralytic consequences of that infection. Primary vaccination should not be given to an individual who has had recent contact with a case of poliomyelitis.

Question: In a passive carrier of poliomyelitis virus does injection of vaccine predispose to infection?

Answer: In the presence of inapparent poliomyelitis infection there may be a slight provoking factor in connection with the use of the Salk vaccine. Since it requires 7 to 10 days for the vaccine to produce antibody, the vaccine cannot be expected to protect the individual from paralytic infection any more than the use of gamma globulin (giving passive immunity) can protect an individual already infected.

Virus Carriers

Question: If there is the possibility of there being infective vaccine, might not children who received the vaccine and who do not become afflicted with poliomyelitis be carriers of the poliomyelitis virus?

Answer: Contact with live poliomyelitis virus, either under natural circumstances or that which may occur by injection of unsatisfactory vaccine in this respect, produces equivalent effects in terms of virus carriage. However, from large-scale field experience, it appears that family contact and other associated cases have been observed only in connection with the administration of lots of vaccine that have contained readily demonstrable quantities of infective virus. Lots of vaccine that are not harmful to the recipient have by the same token not produced recognizable secondary cases.—Jonas E. Salk, M.D.

Question: Is there any danger of close association of uninoculated children with children who were recently inoculated with the Salk vaccine for the first or second time?

Answer: There is no danger of association between uninoculated and vaccinated children. As far as is known a vaccinated child may still become infected, since the vaccine protects against paralysis. However, it is known that animals who are solidly resistant to paralytic infection may still be infected with the virus and excrete it in their feces.

Question: Will not poliomyelitis vaccination subject parents to the disease, which will start epidemics in the child population that has not been vaccinated?

Answer: A properly inactivated vaccine will not subject the parents to the disease; neither can it start an epidemic in the unvaccinated child population.

Vaccine Research Problems

Question: What are the areas where more research is now urgent in the vaccine and control program?

Answer: The following areas of research deserve and are receiving attention: (1) duration in years of immunity to the paralytic disease following vaccination; (2) search for less pathogenic but still highly antigenic strains of virus that might be substituted for those now in use; (3) search for stable strains of attenuated virus that could be used as live virus vaccines; (4) methods of concentrating the vaccine to render the safety test more precise; (5) search for a stable strain of normal human or primate cells, susceptible to poliomyelitis virus, which will grow continuously in cultures and which would eliminate the necessity of importing monkeys from India; and (6) search for better methods of virus inactivation.

Question: I heard a research man state recently that ultraviolet may prove superior to Formalin in inactivating poliomyelitis. What is the basis for this? Is it pH?

Answer: Several investigators are experimenting with the use of ultraviolet irradiation as a method of inactivation of the poliomyelitis virus. This is a physical as opposed to chemical (Formalin) inactivation.

QUESTION: In studies on bacteriophage inactivated by x-ray irradiation there is evidence that the virus may later become activated on standing exposed to ordinary light; inactive virus particles combining to form live virus. Is there any danger of an analogous recombination for inactivated poliomyelitis virus to produce infective virus, particularly in a trivalent vaccine?

ANSWER: In the first place the experiments spoken of were not done by x-ray irradiation but were done by the use of ultraviolet light. Bacteriophages inactivated in this manner were reactivated by exposure to ordinary light. This is not recombination. Bacteriophages inactivated by ultraviolet light and then allowed to adsorb on bacterial cells do, by multiplicity reactivation, produce a few live virus particles. Nothing of this kind has ever been accomplished with animal viruses. On the other hand, when an animal cell is infected by many live, properly marked influenza virus particles, evidence of recombination has been obtained. Finally, there is no reason to believe that poliomyelitis viruses, properly inactivated by formaldehyde solution (Formalin), will become active upon exposure to light, or through the mechanism of multiplicity reactivation, or through recombination.

QUESTION: For how long is there appreciable antibody titer in the blood after a single primary injection of 1 cc. of Salk vaccine?

ANSWER: It is not known for how long there is appreciable antibody in the blood after a single primary injection of 1 cc.

QUESTION: Why is not influenza virus vaccine as effective as poliomyelitis virus vaccine?

ANSWER: This question cannot be answered simply and assumes that influenza virus vaccine is not as effective as poliomyelitis vaccine, which may not be true.—JONAS E. SALK, M.D.

Gamma Globulin

QUESTION: 1. Does gamma globulin ("antipoliomyelitis") provide any safety against "virus introduction or stimulation" due to Salk vaccine? 2. If we assume that there is a slight possibility that live virus particles may escape the safety tests, why not give gamma globulin simultaneously in adequate doses (analogous to the old diphtheria toxin-antitoxin preparation)?

ANSWER: It is not recommended that gamma globulin be given prior to the use of the Salk vaccine.

QUESTION: In the absence of Salk vaccine, should we give prophylactic gamma globulin this summer?

ANSWER: In the event of an epidemic outbreak of poliomyelitis in a community gamma globulin is recommended for mass prophylaxis for the most susceptible age groups.

QUESTION: Why not protect with passive antibody (immune globulin) and infect with attenuated virus enterically?

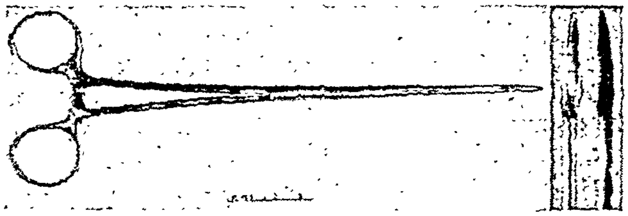
ANSWER: Until such a time as safe attenuated live virus vaccine is available, it is impossible to consider passive immunization with gamma globulin to be followed by the administration of attenuated virus vaccine.

CLINICAL NOTES

ENDOCERVICAL FORCEPS FOR EVALUATION OF THE CERVICAL FACTOR IN INFERTILITY

Allan Palmer, M.D., San Francisco

A new instrument has been devised for the purpose of evaluating the cervical factor in the infertile female. The tenacity of the endocervical mucus often precludes obtaining a satisfactory specimen by suction with a pipette or other available instrument for the purpose of testing its flow elasticity (Spinnbarkeit), spermigration, and postcoital sperm activity. The endocervical forceps shown (figure) enables one to easily obtain an adequate specimen of mucus by simply inserting the closed instrument into the endocervical canal. When the instrument has been placed at the desired level between the internal and external cervical ora, it may be opened slightly, closed and locked, and then withdrawn. The lock on the instrument permits one to lay it aside momentarily without loss of the specimen, if there is to be a momentary lapse of time before it can be examined microscopically. The accurately fitting, smoothly concave opposable tips of the instrument (figure, right) enable one to detach and seal off a specimen of mucus regardless of its variable rheologic characteristics.



Endocervical forceps, with opposable tips (right).

Flow elasticity (Spinnbarkeit) can be measured or evaluated by opening the instrument over a centimeter scale and measuring the length to which the specimen can be stretched before it breaks. The flow elasticity may be regarded as "excellent" if the tips of the instrument can be opened and the mucus stretched to 10 cm. without breaking. The same specimen can then be transferred to a glass slide for microscopic examination. A spermigration test can be made by putting a drop of seminal fluid alongside the mucus, or the mucus may be examined for postcoital sperm activity (Sims-Huhner test). The instrument can also be used, with sterile precautions, for obtaining specimens of cervical mucus for antibiotic sensitivity tests in instances of cervical "bloc." An instrument for the Sims-Huhner test that embodies the principal features of the endocervical forceps has been described by Kerner.[1]

2107 Van Ness Ave.

This instrument was exhibited at the 4th Annual Meeting of the Western Branch of the American Society for the Study of Sterility, Palm Springs, Calif., Nov. 12-14, 1954, and at the 104th Annual Meeting of the American Medical Association, Atlantic City, N. J., June 6-10, 1955.

THE PRESENT STATUS OF POLIOMYELITIS VACCINE

Elsewhere in this issue of THE JOURNAL (page 1239) is a series of papers, discussion, and questions and answers by individuals interested in the use of the "Salk vaccine." At the A. M. A. meeting in Atlantic City in June of this year there was held a panel discussion on prospects for the control of poliomyelitis. The meeting was under the joint sponsorship of the A. M. A. Section on Preventive and Industrial Medicine and Public Health and Section on Pediatrics. Participating were Hart E. Van Riper, moderator, Jonas E. Salk, Thomas D. Dublin, Thomas Francis Jr., and Leonard A. Scheele. The discussion following the presentation of reports by Drs. Dublin, Francis and Scheele was to be opened by James C. McGuinness, Joseph Stokes Jr., and Albert B. Sabin.

After the meeting several papers were received from this joint session, and these are published in this issue of THE JOURNAL. In addition there is a second paper from Leonard A. Scheele that reveals some of the efforts made by the Public Health Service when questions on the usefulness and manufacture of the vaccine used in 1955 were raised. The discussion offered in written statements by Drs. Sabin and Stokes at the time of the meeting pertains to the papers offered at the panel discussion and not to the additional paper by Dr. Scheele. There also is included in this issue a series of questions and answers. The questions are from those raised by the audience of the joint A. M. A. section meeting, and the answers were given and subsequently edited by the members of the panel under the direction of the moderator, Dr. Van Riper.

There probably has not been any medical announcement during this century that has precipitated the discussion and controversy that followed the presentation of the Francis report in Ann Arbor on April 12. Because of the emotional impact of poliomyelitis on the average lay family one can realize how the public responded. At the same time there was a response, not so favorable, from many scientists who claimed such an announcement should have been made first in the usual way that matters of medical scientific importance are released. Also raised were questions by statisticians and epidemiologists. Then, when there appeared the first reports of poliomyelitis following the use of the vaccine the situation really became confusing. Charges and countercharges arose; accusations and counteraccusations followed.

During this period the Board of Trustees and members of the staff of the American Medical Association followed events closely, seeking scientific information for the doctors and their patients. Much that was learned was confidential, and much that was heard was rumor. There were many facts, but often they were shrouded from view by lack of information, sometimes by emotionally tinged presentations. As was pointed out earlier in THE JOURNAL, the Association had indicated its willingness to be helpful, but not much came of the offer. Thus the facts had to be gathered, sorted, and evaluated independently, a task not yet completed. Up to the present time the Association has not issued a statement on the efficacy and use of the vaccine, although it has commended those who have aided in the development of measures intended to control poliomyelitis. There are questions still needing answering, and the Association is continuing its study. In the meantime THE JOURNAL presents the papers offered at the A. M. A. meeting and other additional material for the information they contain.

APPLICATIONS OF MODERN GENETICS

In a review of the accomplishments of modern genetics, Glass [1] points out that in common with other scientists the geneticist possesses the power to effect great changes in the modern world but not the wisdom to evaluate the long-range effects of these changes or to direct the changes in ways that will ultimately produce the best results. In many respects there is no general agreement on the definition of these best results. A simpler problem arose during World War II when it was necessary to find a way to produce penicillin on a large scale. Strains of Penicillium giving a high yield of the antibiotic would grow only on the surface of the culture medium until geneticists produced a mutant by means of irradiation that would grow well throughout the medium. Geneticists also warned but in vain against the production of antibiotic-resistant strains of pathogens before such strains were actually produced. Now faced with a rapidly increasing world population, they are exploring ways of improving the nutritional value of plants and animals used for food. The production a few years ago of hybrid corn is a notable example.

Although the most fascinating phase of genetic study is the improvement of human stock, no means for accomplishing this has as yet been devised. One of the chief difficulties lies in the fact that a large proportion of the genes present in a given person are not manifest and that most characteristics of social significance depend on multiple genes. They are, therefore, rarely inherited *in toto* but when present represent a contribution of genes from both parents. The more genes involved in the transmission of a characteristic the less chance that it will be transmitted to one's offspring intact. Furthermore, a certain gene that in most combinations has a good (or bad) effect may in a certain rarer combination

---

[1] Glass, B.: Genetics in the Service of Man, Johns Hopkins Mag. 6: 2-16 (Feb.) 1955.

e the opposite effect, or, as Glass puts it, "the geneti-
can scarcely appraise the absolute . . . effect of a
e; it must be judged by the company it keeps." Physi-
traits are most nearly determined by heredity, but
inherit only certain potentialities. These can be real-
l only within the limitations of the environment.
ntal traits are more modifiable by the environment
1 physical traits, and social traits or personality, al-
ugh affected by heredity, are altered by environment
1 the greatest ease.

dvances in medical science have aided in the pres-
ation and hence propagation of persons with such
essive genes as those giving a tendency to diabetes,
opia, various allergies, and certain types of deafness.
: proportion of such persons in our civilization is in-
asing. Thus medical science increases the burden it
st carry, because in the past many of these persons
uld have died in childhood or have been so handi-
ped socially as never to have married. Some of the
asures advocated to prevent degradation of human
ck include segregating the sexes to prevent propaga-
1 of institutionalized mentally defective persons, ster-
ation of such persons by ligating the spermatic ducts
the oviducts, and enacting laws against consanguin-
s marriages. None of these have made more than a
ble impression on the problem as a whole.

The more positive approach to the betterment of
nan kind, involving selective breeding of one type or
other, is not likely to gain wide acceptance because of
violent emotional reactions such proposals automati-
ly arouse. Aside from these emotional objections,
ass warns that the widespread use of a "perfect" donor
ough artificial insemination might lead to too great a
formity in a world where diversity is still highly de-
able. Furthermore, because harmful genes are hidden,
idely used donor might spread bad genes throughout
arge segment of the population before they could be
ected. This very thing has happened in the breeding
cattle by artificial insemination. As has been learned
certain royal families in the past, inbreeding brings
essive genes out into the open. If these are harmful,
they are more often than not, inbreeding will increase
: number of persons afflicted. It may be concluded
at it is easier to define good environment than good
redity. So far, the power to change man genetically
ceeds the wisdom needed to know in what direction
netic controls should be applied for best results.

OOD FOUNDATION

Elsewhere in THE JOURNAL (page 1284) is a report
the Committee on Blood of the American Medical
sociation that tells the story of the creation of the
ood Foundation. The creation of this foundation was
important step and reflects the untiring efforts by
M. A. representatives and others over a long period
time. While the Association has been interested in
ood-banking programs for some years, it was in 1953
at the House of Delegates adopted a resolution rec-
mmending the establishment of a coordinated national
ood program organized by the American Medical As-
ciation, the American National Red Cross, and other qualified organizations such as the American Hospital Association, the American Society of Clinical Pathologists, and the American Association of Blood Banks.

There are certain basic principles regarding the supply of blood, its storage and use that are mentioned in the report (page 1284). These are important, but perhaps of no less significance is the fact that the program of the Blood Foundation is voluntary. Therefore its success will depend on the degree of cooperation it will receive from those responsible for the blood-banking facilities in this country. There are many problems to be solved, and solutions may not always come easily; however, one can look with hope to the future in view of the stature of the organizations behind this foundation. Of great importance was the selection of the officers and directors of the Blood Foundation, and the men chosen reflect admirably the energy and leadership provided during the foundation's period of development. The doctors of America can hope to hear much about this comparatively new body in which they should be vitally interested.

MILD POLIOMYELITIS

A recent press release from the health department of the state of New York asks physicians to be watchful for "a non-paralytic polio-like illness." The department reported outbreaks of the disease in several areas within the state. This warning is timely. Such outbreaks have been observed elsewhere and have been commented on repeatedly by members of the Chicago health department. Apparently they are very common in this area, and it is not unusual to learn of a child who developed mild poliomyelitis after a history of playing with other children in his neighborhood but who suffered nothing more than the symptoms seen with a cold or mild intestinal upset. Unless one is on the alert for such histories the disease may be missed and an inaccurate diagnosis made. In fact, the intestinal upset has led to surgery within the abdomen, just as missed instances of pneumonia in the past have resulted in the removal of appendixes.

The press release from New York reads in part: "While the disease has symptoms very similar to those of poliomyelitis, it is very mild, with no paralysis, and recovery is generally within a few days. It occurs most frequently among young children and tends to affect a large number of persons in the same family. . . . The disease is characterized by headache, fever and nausea with moderate stiffness of the neck, an increased number of cells in the spinal fluid and occasional sore throat. Occasionally it has been accompanied by the symptoms of epidemic pleurodynia, or pains in the chest, and, rarely, by sores in the mouth suggesting herpangina."

The request from New York for information from physicians might well be heeded elsewhere in the country if this illness is prevalent. And as for prevalence, one needs only to keep in mind the attitude of a well-known epidemiologist who claims that poliomyelitis during the season is as prevalent as measles during an outbreak of this disease.

ORGANIZATION SECTION

BLOOD FOUNDATION

The Committee on Blood of the American Medical Association has authorized publication of the following report.

The incorporation of the Blood Foundation and the first meeting of its board of directors on May 7 of this year brought to a successful culmination the efforts of the Committee on Blood of the American Medical Association to join together the various voluntary organizations with major interests in the supply of blood and in blood banking. These attempts had their inauguration in June, 1948, when the House of Delegates authorized the Board of Trustees to appoint a liaison committee for the American Red Cross blood-banking program. The name of this committee was subsequently changed to the Committee on Blood Banking at the 1949 meeting and later to the Committee on Blood in December, 1952. The activities of the Committee were spurred by the action of the House of Delegates of the American Medical Association in passing the California resolution in 1953, which recommended the establishment of a coordinated national blood program organized by the American Medical Association, American National Red Cross, and other qualified organizations interested in blood banking.

The events leading up to this decision on the part of the House of Delegates can actually be traced back prior to World War II. At that time blood banking had been established as a practical procedure but most blood banks were operated in conjunction with large hospitals or medical schools. In many cities blood transfusions depended largely upon the existence of a pool of professional donors. Even before Pearl Harbor it was realized that if the country were to be properly prepared for emergency then blood procurement on some nationwide basis would be necessary. From discussions between the Army, Navy, National Research Council, and American National Red Cross a plan for an American Red Cross Blood Donor Service emerged on Feb. 4, 1941. Ten months later the United States was plunged into war and the demand for whole blood and plasma suddenly expanded into a real problem in logistics for the armed forces. Red Cross Blood Donor Centers were established in 35 cities, and 63 mobile units visited other areas on a prearranged schedule; between them these facilities drew a total of 13,326,242 pt. of blood during World War II.

REGIONAL BLOOD BANK PROGRAM

With peace in 1946 the Red Cross abandoned its war-time program of blood collection. Although new blood banks were established in many communities, others returned to the old system of reliance upon professional donors. Physicians trained by service in the armed forces to the ready availability of plasma and whole blood desired similar supplies for their civilian practice. Many chapters of the Red Cross urged reestablishment of the Red Cross system of collection for voluntary donors. In 1947 representatives of the Red Cross appeared before the Board of Trustees of the American Medical Association relative to the establishment of a national blood program by the Red Cross. The proposed program was to establish a system to furnish whole blood and blood derivatives throughout the country. The Board of Trustees agreed to recommend approval in principle of the Red Cross plan for the establishment of a national blood program with the understanding that the operation should be maintained on a community level with the approval of the county medical societies concerned. The matter was referred to the House of Delegates, and the action of the Board was affirmed by the House of Delegates in June of that same year. Launching of this program by the Red Cross created many unseen problems requiring a considerable degree of attention, exercise of diplomacy, and formulation of principles and policy by the Board of Trustees, the A. M. A. Committee, and the House of Delegates. Criticism of the Red Cross Regional Blood Bank program came from many sources; after considering these criticisms in June, 1948, the House of Delegates reaffirmed its previous action of approval but defined what was meant by approval in principle in the following words:

"Realizing the possibility of a national emergency requiring large amounts of blood in the treatment of civilian and military casualties and realizing the unique position of the American Red Cross in disaster relief, your committee is of the opinion that no change should be made at this time in the 'approval in principle' of the participation of the American Red Cross in the national blood program voted at the Interim Session in January 1948.

"However, your committee would call attention of the House to the fact that long before the Red Cross entered this field of medical practice many previously established blood banks had been operating successfully and adequately under strictly local supervision and had rendered invaluable services to the community. To disturb such independent local units would, in the opinion of your committee, be unwise and disastrous, for they have repeatedly demonstrated their ability to meet local and regional needs. Furthermore, they have demonstrated the practicability of free enterprise and local initiative.

"From the testimony presented at the several hearings before your reference committee, it is quite evident that there has been confusion and misunderstanding between local chapters of the Red Cross and the medical profession at local levels.

"It is the opinion of your reference committee that the 'Approval in Principle' be construed as follows: First, local control must be by the county medical society. Second, the local medical society should be the initial contact in the contemplation of inauguration of a new blood bank. Third, no publicity nor news releases shall be released except by mutual consent of the local county medical society and the local chapter of the American Red Cross. Fourth, difference of opinion in establishment or operation of a blood bank in either administrative or technical detail shall be arbitrated at state levels by joint committees from the state medical society and the American Red Cross."

PRINCIPLES REGARDING BLOOD SUPPLY AND BANKING

In the period between the formation of the liaison committee in 1948 and the formation of the Blood Foundation in 1955, the Board of Trustees on recommendations from the Committee on Blood has requested the House of Delegates to adopt certain basic principles regarding the supply of blood and blood banking: 1. The primary interest of physicians in relation to blood and blood banking is to secure the widest, most efficient and economical supply of safe usable blood and its derivatives for the American people. 2. In establishing blood-banking systems the principle of local determination by county medical society endorsement is desirable. 3. Blood replacement responsibility is regarded as a problem of the family of the recipient, his friends, and various organizations of which he is a member, as well as the community. 4. The interbank exchange of blood on a unit-for-unit basis is felt necessary to develop an integrated national system of blood banks. 5. Nonprofit operation of blood banks but with service cost borne by the patient has been repeatedly emphasized. Possibly restatement of the words used in the June, 1952, report accepted by the House of Delegates will be most clarifying: "Since blood is derived from human beings only, our aim should continue to be directed at having no profit from trafficking in whole blood itself; however, all services rendered cost something and are paid for by or on behalf of every recipient of such services. The service charge should cover all costs of the operation including depreciation and expansion reserves, but the realization of profit for the support of other institutional needs should be discouraged."

In the formulation of the bylaws of the Blood Foundation the Committee on Blood has fought for and has succeeded in having included all of the principles adopted by the House of Delegates with but one modification. While the unit-for-unit exchange of blood between blood banks is accepted as the principle, it is recognized that because of the perishable nature of blood there is a certain percentage of loss in all blood banks. The larger the blood bank the lower this percentage of loss would be, although there is an irreducible minimum. Smaller d banks because of their lesser volume and because of the ssity for maintaining a supply of all types of blood en- ter a larger percentage loss. Therefore it was recognized he board of directors of the Blood Foundation that some stment must be made in the system of unit-for-unit ex- ge because replacement of a borrowed unit of processed d to a small bank by a larger bank actually involves less stment on the part of the large bank. This matter is pres- under consideration by a special committee appointed by resident of the Blood Foundation.

PROGRAM

he program of the Blood Foundation is entirely voluntary its success or failure will depend upon the degree of co- ation it will receive from the blood-banking facilities of the ted States. There are many attendant problems to be solved the board of directors in this trying, occasionally vexing, field.

he leadership furnished by the Committee on Blood in these tiations with the American National Red Cross, American pital Association, American Society of Clinical Pathologists, American Association of Blood Banks is probably best sted to by the fact that the Chairman of the Committee on d, Dr. Leonard Larson, has served as chairman of the joint tiating committees and has now been elected the first presi- of the Blood Foundation. This in no way should be con- ed as deprecation of the efforts of the representatives of the erican National Red Cross, the American Hospital Associ- n, the American Society of Clinical Pathologists, and the erican Association of Blood Banks. All representatives dur- these meetings have exhibited high-minded principle and arnest desire to negotiate a workable solution to the prob- s of blood banking. Acknowledgment too should be made ormer members of the Committee, Drs. William A. Coven- James Q. Graves, James Stevenson, and especially the ner co-chairman Herbert Ramsey for their devoted unselfish ice.

fficers and directors of the Blood Foundation are Leonard Larson, M.D., president; Merlin L. Trumbull, M.D., vice- ident; Karl S. Klicka, M.D., treasurer; and David N. W. nt, M.D.; Donald H. Kaump, M.D.; Walter B. Martin,).; James J. Griffitts, M.D.; Mr. Charles H. Kellstadt; Edwin rosby, M.D.; and Frank W. Konzelmann, M.D.

V TELEVISION PROGRAM ON MEDICAL RESEARCH

Medical Horizons," a new half-hour television series, pre- ed by Ciba Pharmaceutical Products, Inc., in cooperation the American Medical Association, will be premiered on nday evening, Sept. 12, over ABC-TV. The new documentary es will present specific accomplishments in the field of licine brought about by the teamwork of modern medical arch, education, and practice. The program will be presented h Monday from 9:30 to 10:00 p. m., New York time, on a work of 45 ABC-TV affiliated stations for a minimum of 26 ks. Stations in the Pacific and Mountain time zones will eive the program on a two-week delayed basis via Kinescope . Emanating via live remote telecasts from medical institu- s and research centers, the series will be packaged by the Walter Thompson Company under producer-director Fred ney. "Medical Horizons" will be under the supervision of William T. Strauss of Ciba.

. WERMER LEAVES FOR NEW POST

r. Paul L. Wermer, who has been with the A. M. A. dur- the past six years as Secretary of the Committee on Re- rch and the Committee on Blood, left July 15 to take a posi- as vice-president and director of product development for rner-Chilcott Laboratories, Morris Plains, N. J. As Secre- y of the Committee on Research, Dr. Wermer assisted in dies of breast cancer, worked on various studies in connection h diabetes and pregnancy, and established a registry for blood crasias; he presently is engaged in setting up a registry for orting toxic reactions to therapeutic agents.

FEDERAL MEDICAL LEGISLATION

First Session, 84th Congress

National Hospital Week

Senator Hill (D., Ala.) and Senator Thye (R., Minn.), in S. Con. Res. 23, and Congressman Priest of Tennessee, in H. Con. Res. 113, would have Congress request the American people to "cooperate in a voluntary effort to observe National Hospital Week." These measures were referred favorably and passed and signed by the President. These bills were handled in the Senate by the Committee on Public Welfare and in the House by the Interstate and Foreign Commerce Committee.

Federal Aid to State Soldiers' Homes

Congresswoman Rogers (R., Mass.), in H. R. 5378; Congressman Ford (R., Mich.), in H. R. 5564; Congressman Forand (D., R. I.), in H. R. 5930; Senator Langer (R., N. D.), in S. 1780; and Senator Green (D., R. I.), in S. 1916, propose to require that at least one-half of the beds of each state soldiers' home be available for domiciliary care, if federal subsidies are obtained. The Senate measures were referred to the Committee on Labor and Public Welfare, the House measures to the Committee on Veterans' Affairs and the Committee on Armed Services.

Graduate Traineeship for Nurses

Congressman Bolton (R., Ohio), in H. R. 648, would authorize the surgeon general of the Public Health Service to provide traineeships for graduate professional nurses for training to teach in the various fields of nurses' training or to serve in an administrative or supervisory capacity in the various fields of nursing. This bill was referred to the Interstate and Foreign Commerce Committee.

Veterans Chiropractic Treatment

Senator Magnuson (D., Wash.), in S. 1768, proposed to extend chiropractic treatment through the Veterans Administration to veterans. His bill states: "That whenever any person is entitled by law or regulation to receive medical care by or through the Veterans' Administration, he shall, if he so elects, have the right to receive chiropractic care and the Chief Medical Director shall make available the services of qualified chiropractors." This bill was referred to the Committee on Labor and Public Welfare.

Lengthening Presumption of Service Connection for Arthritis, Psychoses, and Multiple Sclerosis

Congressman Henderson (R., Ohio) has introduced, in H. R. 5719, a measure that would "amend the Veterans' Regulations to provide that arthritis, psychoses, or multiple sclerosis developing a 10 per centum or more degree of disability within three years after separation from active service shall be presumed to be service-connected." The present presumption period for arthritis is one year, for psychoses two years, and multiple sclerosis two years. This measure was referred to the Veterans' Affairs Committee.

Presumption of Service Connection for Holders of Purple Heart

Congressman Siler (R., Ky.), in H. R. 5667, would amend the Veterans' Regulations to provide that "if a person has been awarded the Order of the Purple Heart and is not otherwise suffering from a service-incurred or service-aggravated disease or disability, 10 per centum or more in degree, he shall be deemed to be suffering from such a disease or disability, 10 per centum in degree." This would apply only to persons with the Order of the Purple Heart after the enactment of the proposed legislation. This bill was referred to the Committee on Veterans' Affairs.

Practical Nurse Training

Congressman Huddleston (D., Ala.) has introduced an identical measure with S. 929, reported in The Journal, April 30, 1955, page 1618. This will amend the Vocational Education Act to establish a training program for practical nurse and auxiliary personnel under the Commissioner of Education in the Department of Health, Education, and Welfare. This bill was referred to the Committee on Education and Labor.

Prepared by the Washington Office of the American Medical Association.

MEDICAL NEWS

CALIFORNIA

Physicians' Orchestra.—A Physicians' Symphony Orchestra is being organized in San Francisco under the conductorship of Mr. Murray Graitzer. The first meeting was held in the auditorium of the San Francisco Medical Society's headquarters June 7. For information, call Dr. Charles P. Lebo, YUkon 6-4370.

Health Department Needs Physicians.—The Los Angeles City Health Department announces the availability of two administrative posts for physicians with public health experience and several positions in clinical medicine. Applications are being received by the commissioners of the board of health for the position of medical director, a post involving the direction of communicable disease control, maternal and child health, adult health, laboratories, and public health nursing. Salary range is from $797 to $992 a month. The department is seeking also a qualified epidemiologist with formal training in public health, special experience in communicable disease control, and administrative abilities. This position pays $715 to $889 a month. Openings for chest specialists for clinical duties in the tuberculosis control service are available at salaries ranging from $608 to $755. None of these positions requires a competitive Civil Service examination. Applicants will be interviewed and appointed on the basis of training, background, and ability. For information, qualified physicians may contact Dr. Hamlet C. Pulley, Executive Officer, Los Angeles City Health Department, 111 E. First St., Los Angeles 12.

CONNECTICUT

State Medical Election.—The Connecticut State Medical Society recently elected Drs. Oliver L. Stringfield, Stamford, president; Ralph T. Ogden, Hartford, president-elect; John D. Booth, Danbury, first vice-president; John F. Kilgus, Litchfield, second vice-president; and reelected Drs. Creighton Barker, New Haven, executive secretary; Frank H. Couch, Cromwell, treasurer; and Stanley B. Weld, Hartford, editor of the *Connecticut State Medical Journal*. At a special ceremony during the annual dinner, 50-year pins were awarded to Drs. David R. Lyman, Wallingford, Harry C. Clifton, West Hartford, and Irwin Granniss, Northford.

IDAHO

Rheumatic Fever Program.—A $100,000 free penicillin program to curb rheumatic fever in Idaho was recently approved by the Idaho Heart Association and Idaho State Department of Public Health, which will share the costs equally and provide tablets to physicians for use in the medically indigent. The action was taken at the annual scientific assembly of the Idaho Heart Association, where the following officers were elected for the coming year: Dr. Harvey A. Hatch, Idaho Falls, president; Dr. Luther C. Thompson, Twin Falls, president-elect; Dr. Joseph Saltzer, Nampa, vice-president; Dr. Paul R. Sharick, Boise, secretary; and Mr. William A. Goodall, Boise, treasurer.

ILLINOIS

Personal.—Dr. Werner Tuteur, clinical director at Elgin State Hospital, Elgin, has been given a grant-in-aid of $3,000 by Smith, Kline and French Pharmaceutical Company, to investigate further possibilities of Thorazine and reserpine on highly disturbed psychotic patients.

Epilepsy in Industry.—The Illinois Epilepsy League has initiated a drive to encourage wider employment of persons with epilepsy through its sponsorship of an Industry Committee for Employment, consisting of industrialists, business men, and the pres
At an Epilepsy in Industry Conference in Chicago on May 2
a panel discussion, "The Nature of the Problem," was presen
by Dr. Frederick W. Stamps, University of Illinois, Chicago, wh
discussed the medical aspects; Dr. Edward D. Schwade, Milwaukee, who covered the social and medicolegal phases; an
Miss Virginia Gibson, of the Division of Services for Crippl
Children of the State of Illinois, who related the problem t
public health. At the luncheon session the Hon. Maxwell M
Rabb, Washington, D. C., Secretary to the President's Cabinet,
stressed the social and economic importance of providing jo
opportunities for rehabilitated workers with chronic disorders o
other handicaps, and Dr. Abe B. Baker, Minneapolis, chairman
of the Committee for Research in Neurological Disorders
explained the process of restoring the neurologically disable
to productivity. The afternoon session was devoted to employment, with a panel discussion of "Epilepsy in Industry," in which
Dr. Frederic A. Gibbs of the Consultation Clinic on Epileps
at the University of Illinois, Chicago, and Dr. Joseph H. Chiver
medical director of the Crane Company, Chicago, spoke o
medicine and on industrial medicine respectively. Dr. William G
Lennox, Boston, was cited for a lifetime of teaching, researc
and leadership in epilepsy. Dr. Nicholas P. Dallis, Toledo, Ohi
who recently devoted many weeks to a dramatic exposition
epilepsy in his syndicated comic strip, "Rex Morgan, M.D.
was named for his outstanding contribution to public educatio

Chicago

Alumni Honored.—At the annual alumni dinner of the Medi
Alumni Association, University of Chicago School of Medici
June 9, Dr. Russell M. Wilder, Rochester, Minn., was present
with the Gold Key of the Medical Alumni Association, and D
Paul C. Bucy, Chicago, and Dr. David Bodian, Baltimo
received Distinguished Service awards.

Plastic Surgery of Head and Neck.—The American Otorhi
logic Society for Plastic Surgery announces its second gradu
course in plastic surgery of the head and neck Oct. 7-9 at
Morrison Hotel. The course will be limited as to the num
of participants, who will be recognized surgeons speciali
exclusively in otolaryngology, ophthalmology, and plastic s
gery of the head and neck. For information, write Dr. Le
Joel Feit, Secretary, 66 Park Ave., New York 16.

New Vice-President at University.—Herbert E. Longeneck
Ph.D., dean of the graduate school at the University of Pi
burgh since 1946, has been appointed vice-president of t
University of Illinois in charge of the Chicago Professio
Colleges to fill the post vacant since July, 1953. Dr. Longenec
will be administrative head of the university's colleges of me
cine, dentistry, and pharmacy, graduate college in Chica
school of nursing, research and educational hospitals, clini
institutes, and other health science units at the West Side Medi
Center. Dr. Longenecker served as a graduate assistant a
later as an instructor in Pennsylvania State College from 19
to 1936; National Research Council Fellow at the Universi
of Liverpool, England, from 1936 to 1937, University
Cologne, Germany, in 1937, Queen's University, Canada,
1938; and then came to the University of Pittsburgh, where h
posts have included a professorship of biochemistry and a d
rectorship of the Buhl Foundation Project.

IOWA

Series of Medical Forums.—A series of five medical forums w
recently presented in Davenport under the joint sponsorship o
the Scott County Medical Society and Davenport Newspape
Inc. The opening and closing meetings were "for women only
sessions, and the others dealt with problems of dentistry, psychiatric treatment, and heart disease. About 2,000 women attende

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

closing session, at which Dr. Walter J. Balzer served as lerator for a panel that included Drs. Arline M. Beal, Walter oley Jr., Merrill M. Benfer, and Howard A. Weis, Daven- . The Iowa State Medical Society presented the newspapers its first Community Service awards. A second series of th forums is projected.

SAS

pensation Law Amended.—The Kansas Workmen's Com- ation Law has been amended to provide treatment of an red workman in the total amount of $2,500 and extension he 120 day limitation on medical treatment for a longer od of time in extreme cases, at the discretion of the com- ioner. The amendment provides also that the unreasonable sal of the workman to submit to an operation for surgical ir of a traumatic hernia shall deprive such workman of any fits under the act, except that in the event such hernia is erable, compensation shall be paid at the rate of 60% of average weekly wage during 12 weeks. The physician ex- ning an employee for an employer is required to furnish employee, on request, and within 15 days after such nination, with a copy of the identical medical report fur- ed the employer.

INE

e Medical Election.—Newly elected officers of the Maine lical Association include Dr. Martyn A. Vickers, Bangor, ident; Dr. Armand Albert, Van Buren, president-elect; and ner M. Kennard, Portland, secretary-treasurer.

liology for Industry.—Colby College, Waterville, will present third annual Course in Industrial Deafness Aug. 7-13. The rse, which will be given for 20 participants, will train person- in conducting conservation of hearing programs in noisy istries. Dr. Frederick Thayer Hill will be director of the rse. Registrants will live on the college campus. Tuition fee 200 includes board and room. Applications should be made Ir. William A. Macomber, Director, Division of Adult Edu- on and Extension, Colby College, Waterville.

W YORK

demy of Preventive Medicine.—The New York State demy of Preventive Medicine was organized at a meeting in falo May 11. Dr. Vivian A. Van Volkenburgh, Albany, was ted president; Dr. Franklin M. Foote, New York, president- t; Dr. Morton L. Levin, Albany, vice-president; Dr. Walter Levy, Albany, secretary-treasurer; and Drs. Joseph H. naman, Garden City, Michael Antell, New York, and Milton ly, Hornell, directors for three year, two year, and one year ns respectively. Membership is limited to physicians who diplomates of the American Board of Preventive Medicine, ding or employed in New York State. Qualified applicants eligible for charter membership by application until Dec. 31, 55. After that date, eligible applicants can be elected to mbership. Forms for charter membership may be secured m Dr. Walter C. Levy, Secretary-Treasurer, New York State ademy of Preventive Medicine, 353 Broadway, Albany.

rsonal.—Dr. Freeman S. O'Brien has resigned as health officer the village of Wappingers Falls because of ill health, and . Albert R. Scafuri, assistant health officer during the recent ence of Dr. O'Brien, has been appointed health officer.——— . Giles F. Filley, formerly director of the department of ysiology, Trudeau-Saranac Institute, Trudeau, will join the partment of medicine at the University of Colorado Medical nter, Denver, Sept. 1. Dr. Filley will also serve as clinical ysiologist at the Colorado Foundation for Research in berculosis.———Dr. James A. Halsted has been appointed chief professional services at the Veterans Administration Hospital, racuse, and associate professor of medicine at the State iversity of New York College of Medicine at Syracuse. He s formerly a member of the staff at the Veterans Administra- n Hospital in Los Angeles and at the faculty of the Univer- y of California at Los Angeles Medical Center.———Dr. C. uart Welch, associate professor of surgery, and Dr. Ralph D. lley, instructor in surgery, Albany Medical College, read papers on new advances in surgery before the third Medical Society Congress, held in Rabat and Casablanca, Morocco, April 12-16, under the sponsorship of the Morocco Medical Society.

New York City

Appointments for Dr. Sheehan.—Dr. Donal Sheehan, acting director of the New York University-Bellevue Medical Center since 1951, was recently named dean of the College of Medicine and of the Postgraduate Medical School and deputy director of the medical center—duties that had been shared by Dr. Currier McEwen, dean of the medical college, and Dr. Robert Boggs, dean of the Postgraduate Medical School. Dr. Sheehan assumed his new responsibilities on July 1, when, at his own request, Dr. McEwen returned to teaching and Dr. Boggs' resignation became effective. Dr. Sheehan was acting dean from 1943 to 1945.

Gift for New Library.—An anonymous gift of $100,000 has been made for the new library at New York Medical College, Flower and Fifth Avenue Hospitals. The library, part of the six-story building being constructed on 105th Street off Fifth Avenue by the college as the first step in the million dollar expansion program, will replace the present medical library on the second floor of the college building on Fifth Avenue and 106th Street. The library will be integrated with the Flower-Fifth Avenue Hospital record library, so that clinical studies can easily be made of case histories in conjunction with textbooks and medical journals. The hospital case histories will be on microfilm. A room will be set aside in the library for audiovisual aids, including a microfilm projector, motion picture projector and screen, lantern slides, and tape recorders. A periodical room and a second study room will complete the library.

OHIO

Course on Occupational Skin Problems.—The Institute of Industrial Health of the University of Cincinnati announces that the course of instruction in occupational skin problems will be presented Oct. 10-14. The program will be divided into three daily sessions—morning lectures and clinical demonstrations, afternoon field instruction in industrial plants, and evening panel discussions. Physicians interested in attending the course should write to Secretary, Institute of Industrial Health, Kettering Laboratory, Eden and Bethesda avenues, Cincinnati 19. Attendance will be limited.

Personal.—Dr. Walter J. Zeiter, assistant to the executive director of the Cleveland Clinic Foundation, was recently named medical coordinator, with the responsibility of coordinating the medical and surgical services with the administrative departments. Dr. Zeiter, who is president of the National Association of Clinic Managers, joined the staff of the Cleveland Clinic Foundation in 1937 as head of the department of physical medicine and rehabilitation and established the foundation's training school for physical therapists. He has been a member of the A. M. A. Council on Physical Medicine and Rehabilitation since 1951.

TEXAS

Chauncey Leake Goes to Ohio State.—Chauncey D. Leake, Ph.D., executive director, University of Texas Medical Branch at Galveston, has been appointed assistant dean of the college of medicine and professor of pharmacology at Ohio State University, Columbus. Dr. Leake has been at the Texas Medical Branch since 1942, when he was named vice-president. He will assume his new duties Sept. 1, succeeding Dr. John A. Prior, who asked to be relieved of this position to devote full time to teaching, research, and patient care in the department of medicine in which he is a professor and director of the division of chest diseases. Dr. Leake has taught physiology and pharmacology at the University of Wisconsin in Madison and at the University of California, Berkeley-San Francisco, where he served as lecturer in medical history and librarian of the medical school. He is on the editorial board of the *Archives of International Pharmacology* and is chairman of the committee of problems of alcohol of the National Academy of Sciences.

WASHINGTON

Course in Paralytic Respiratory Failure.—A postgraduate course in the Management of Acute Paralytic Respiratory Failure will be presented at the University of Washington School of Medicine, Seattle, Aug. 19. Treatment methods for poliomyelitis, polyneuritis, nervous system poisoning, and related disease states will be discussed and new equipment demonstrated. Dr. Russell R. de Alvarez, professor of the department of obstetrics and gynecology, will serve as chairman for the course, which will be sponsored by the University of Washington School of Medicine, Washington State Medical Association, Washington State Department of Health, and by a grant from the National Foundation for Infantile Paralysis. The course (fee, $10) is open to graduates of medical schools approved by the Council on Medical Education and Hospitals of the American Medical Association. Checks made payable to the University of Washington should accompany the application and be addressed to the Division of Postgraduate Medical Education, University of Washington School of Medicine, Harborview Hospital Annex, 325 Ninth Avenue, Seattle 4.

WEST VIRGINIA

Personal.—Drs. Walter L. Barbour, Whitesville, Merwin B. Moore, Huntington, and Ozro H. Bobbitt, Charleston, have been elected to honorary life membership in the West Virginia State Medical Association.

State Medical Meeting.—The West Virginia State Medical Association will hold its annual meeting Aug. 18-20 at the Greenbrier, White Sulphur Springs, under the presidency of Dr. James P. McMullen, Wellsburg. The convention will be preceded by the Freedom of Information Clinic Wednesday evening. The clinic, with its six member panel, composed of representatives of the press and the medical profession, and its audience participation, supplants the public relations meeting customarily held. It will be addressed by Mr. Leo E. Brown, Chicago, A. M. A. Director of Public Relations, and Mr. Peyton B. Winfree Jr., executive editor of the *News and Advance*, Lynchburg, Va. All general sessions will be held in the theater of the newly completed air-conditioned convention unit. Sound motion pictures on scientific subjects will be shown each morning at 8:15. The convention will open Thursday at 9:15 a. m. The following symposium on hypertension will be presented by members of the faculty of Duke University School of Medicine, Durham, N. C.:

Etiology and Surgical Treatment of Hypertension, Keith S. Grimson.
Pharmacology of Drugs Used in Hypertension, James P. Hendrix.
Medical Therapy of Hypertension, Edward S. Orgain.

A panel discussion and question and answer period will follow the symposium. Dr. Robert U. Drinkard Jr., Wheeling, will serve as moderator at this session. The following program is scheduled for Friday morning, with Dr. Richard E. Flood, Weirton, as moderator:

Present-Day Problems Concerned with Antibiotic Therapy, Chester S. Keefer, Boston.
Differential Diagnosis of Hip Joint Disease in Children, Marcus J. Stewart, Memphis, Tenn.
Management of Intractable Peptic Ulcer, Charles M. Caravati, Richmond, Va.

The final general session, Saturday morning, will have as moderator Dr. Richard W. Corbitt, Parkersburg, who will preside over the following program:

Malignant Lesions of the Colon, Isidor S. Ravdin, Philadelphia.
Injuries of the Ureter and Bladder During Pelvic and Colon Surgery, John L. Emmett, Rochester, Minn.
The Anesthesiologist in the Medical-Surgical Team, Curtiss B. Hickcox, Hartford, Conn.

The section on urology has scheduled a symposium for Friday afternoon, when guest speakers will be Dr. Elmer Hess, Erie, Pa., President of the American Medical Association, and Dr. John L. Emmett, professor of surgery at the Mayo Foundation Graduate School of the University of Minnesota, Rochester. Dr. Hess will also address the final meeting of the house of delegates Saturday, 3:30 p. m. His subject will be "Medical Crisis." Dr. Isidor S. Ravdin, Philadelphia, guest speaker at the meeting of the section on surgery Friday afternoon, will discuss "Gastric Ulcer and Gastric Cancer," and the guest speaker at the meeting of the section on orthopedic surgery, which will be held simultaneously, will be Dr. Marcus J. Stewart, Memphis, Tenn., who will have as his topic "Treatment of Fractures of the Hip with Non-Union."

Numerous social events have been planned. These will include the annual cocktail party, which will be given under the sponsorship of the Kloman Instrument Company, Inc., of Charleston, Saturday, 7:30 p. m.; and a "Gay Nineties" party, which has been arranged by the Woman's Auxiliary for Friday, 10 p. m. An innovation of the annual golf tournament will be a separate tournament for guest physicians and representatives of technical exhibits.

WYOMING

State Medical Election.—The Wyoming State Medical Society recently elected Dr. Russell I. Williams, Cheyenne, president Dr. Joseph S. Hellewell, Evanston, president-elect; Dr. Harla B. Anderson, Casper, vice-president; Dr. Benjamin Gitlitz Thermopolis, secretary; and Dr. Carleton D. Anton, Sheridan treasurer.

GENERAL

Cancer Research Project.—A joint attack on malignant mela noma has been organized between the University of Texas M. D Anderson Hospital and Tumor Institute in the Texas Medica Center, Houston, and the University of Oregon Medical Schoo Portland. The "Melanoma Study Section," organized in Decem ber, 1954, is the second such research group organized by th University of Texas M. D. Anderson Hospital. The first was th "Cancer Eye Study Section," for the study of squamous ocul carcinoma in cattle. The National Cancer Institute has recom mended approval of grants for the study section.

Heart Sound Tape Library.—A library of tape-recorded hea sounds and murmurs is being established by the American Hea Association for use in undergraduate and postgraduate medic education. The association's committee on auscultatory ph nomena announces that the library will include 10 teaching ree and 34 different heart sounds and murmurs available in loc form at 1⅞ and 7½ in. per second. The tapes are expected be ready for circulation around Sept. 1. Information on use the tapes, as well as descriptive materials on their content, ca be obtained from the Medical Division, American Heart Assoc ation, 44 E. 23rd St., New York 10.

The Lalor Foundation Awards.—The Lalor Foundation (44 Lancaster Pike, Wilmington, Del.) announces awards up $1,100 each to 23 faculty members of American and Canadia colleges and universities for 1955 summer research and study i the biological sciences. The Marine Biological Laboratory Woods Hole, Mass., has announced appointment of one Senio Lalor Fellow and six Postdoctorate Lalor Fellows for the sum mer of 1955 under its agreement with the Lalor Foundatio It is anticipated that announcement will be made in Octobe regarding the next series of awards to be offered to college an university faculty members for research in the biological scienc during the summer of 1956.

Request Names of Multiple Sclerosis Victims.—A nationwid search is being conducted by some 2,750 JayCee chapters i cooperation with the National Multiple Sclerosis Society an its 70 chapters, to reach an estimated 250,000 unknown multipl sclerosis victims and put them in touch with the national society Physicians and multiple sclerosis sufferers and their relatives ar urged to advise the National Multiple Sclerosis Society of th names and addresses of all multiple sclerosis victims. The iden tity of any person reported to the society will be kept confi dential. Dr. Hans H. Reese, Madison, chairman of the medical advisory board of the National Multiple Sclerosis Society, will provide information for physicians interested in the search for victims. Interest of the JayCees in the program stems primarily from the fact that the disease is reported to strike 1 in every 400 young adults. The JayCee age group is from 20 to 35.

ew Periodical on Alcohol Problems.—The International In- tute for Research on Problems of Alcohol has announced that official organ will be the *International Journal of Alcohol d Alcoholism*, which will be published three times annually. e new periodical will present surveys of the problems, achieve- ents, and statistics of individual countries, beginning with rveys on Austria and Canada in the June issue. The journal 'll also feature current and classified bibliographies of the orld literature. The journal will publish in English, French, erman, Italian, and Spanish. The international subscription ice is 30 shillings; in the U. S. A., $6. Editorial correspondence ould be addressed to H. Pullar-Strecker, M.D., Wyke House, leworth, Middlesex, England. Business correspondence should addressed to the publishers, Blackwell Scientific Publications, Broad St., Oxford, England, or to the American publishers, harles C Thomas, 301 E. Lawrence Ave., Springfield, Ill.

ardiac Research Grants.—Applications by scientific investi- tors for support of research to be undertaken during the year ginning July 1, 1956, are being accepted by the American eart Association. The application deadline for research fellow- ips and established investigatorships is Sept. 15 and for grants- -aid, Nov. 1. Established investigatorships are awarded for riods of up to five years, subject to annual review, in amounts nging from $6,000 to $9,000. Research fellowships are awarded young men and women with doctoral degrees for periods of e to two years to enable them to train as investigators under perienced supervision (annual stipends, $3,500-$5,600). Grants- -aid are made in varying amounts, not to exceed $10,000, to perienced investigators to provide support for specific projects. areer investigators are selected by the research committee, ther than by application. Information may be obtained from e Medical Director, American Heart Association, 44 East rd St., New York 10.

adiological Conference.—The 17th Midsummer Radiological onference of the Rocky Mountain Radiological Society will nvene at the Hotel Shirley-Savoy, Denver, Aug. 18-20, under e presidency of Dr. Alfred M. Popma, Boise, Idaho. Guest eakers and their first presentations include:

Warren W. Furey, Chicago, The Radiologist—Quo Vadis?
Higdon B. Elkins, Iowa City, Use of Radioactive Gold Intra-Abdominally in the Treatment of Carcinoma of the Ovary.
George Z. Williams, Bethesda, Md., Effects of X-Ray on the Mechanism of Carcinogenesis in the Liver.
Isadore Meschan, Little Rock, Ark., Review of Cobalt 60 and Its Interstitial Uses.
John W. Hope, Philadelphia, Roentgen Fables of Infants and Children. Part I: The Unfilled Chest, the Bulgy Neck and the Shadowy Belly.

ngle author presentations by invitation will include:

Semiconductors in the Field of Radiology, E. Dale Trout, Ph.D., Milwaukee.
Clinical Stationary Field Therapy with a Cobalt 60 Unit. Part I and Part II, Gilbert H. Fletcher, Houston, Texas.
Radiological Demonstration of Tumors of Sinuses and Nasopharynx, John P. McGraw, Houston, Texas.
Some Internal Abdominal Hernias, Cyrus W. Partington, Denver.
New Concept of Treatment of Breast Cancer, Bertram V. A. Lowbeer, San Francisco.
Cerebral Angiography in Intracranial Vascular Lesions, Homer G. McClintock, Denver.
Translumbar Aortography in Disease of the Aorta, Robert V. Elliott, Denver.
Uterosalpingography: Studies in Sterility, Thomas M. Fullenlove, San Francisco.

uest speakers will participate at the luncheon sessions each ay. A guest speakers' dinner (informal) Thursday, 6 p. m., will e followed by a joint meeting with the Denver Medical Society Dr. Cyrus W. Anderson, Denver, president). Dr. Furey, who president of the American College of Radiology, will serve s moderator for a session on roentgen film diagnoses with rs. Meschan, Hope, Ralph C. Moore, Omaha, and John P. IcGraw, Houston, Texas, as panelists. The Colorado Radio- ogical Society will be host at the social hour following the cientific session. The banquet (strictly informal) is scheduled or Friday, 7:30 p. m., after a social hour. Dr. Popma will reside, and Dr. John S. Bouslog, Denver, will serve as toast- naster. Saturday will be devoted to a trip to Central City, with linner at the Teller House, 6 p. m., and the play, "Bus Stop," t the Central City Opera House, 8:15 p. m.

Prevalence of Poliomyelitis.—According to the National Office of *Vital Statistics*, the following number of reported cases of poliomyelitis occurred in the United States and its territories and possessions in the weeks ended as indicated:

Research in Mental Health.—The Ford Foundation has announced an extensive program of support for research in mental health. Programs eligible for such support will include: personality dynamics and development; biological, physiological, and somatic aspects of mental health; social and community aspects; studies in therapy; and children's disorders. The research programs may be located in any qualified institution in the U. S. or abroad. It is estimated that the programs will operate within the range of $50,000 to $150,000 a year and that the average will fall somewhat below $100,000 a year. The criteria to be used in selecting programs for support are: clear relevance for the field of mental health; specific nature and content of the program; past and potential quality of performance of personnel, with special attention to qualifications of the program's leadership; proper organizational arrangements within the institution; provision of research training in connection with the research program; integration of attack on the problem against other disciplines or research approaches, where appropriate; complementary relationship to other research programs in the same or related fields; and no displacement of existing funds. Applicants are asked to submit a full description of their proposed programs of research. Each application should be submitted in eight copies, accompanied by an official letter of submission from the principal administrative officer of the sponsoring institution. Applicants who are unable to submit proposals by Sept. 1 but intend to do so later are asked to send a statement to that effect by that date to the Secretary, Ford Foundation, 477 Madison Ave., New York 22.

Postdoctoral Fellowships.—The award of a second group of postdoctoral fellowships during the current calendar year will be made by the National Science Foundation Oct. 20. Applications will be received through Sept. 12. The postdoctoral fellowships are awarded to U. S. citizens who will begin or continue their studies at the postdoctoral level in the life and physical sciences (including interdisciplinary fields) at any time within one year after the announcement of awards. Selection will be made solely on the basis of ability as shown in academic records, in written evaluation of each individual by faculty advisers or other qualified observers, and in a proposed plan of research. The stipend for National Science Foundation postdoctoral fellowships is $3,400 a year. Dependency allowances are made to all married fellows. A limited allowance to aid in defraying cost of travel will be paid as will tuition and certain fees collected from individuals of similar academic standing. Application materials may be obtained from the Fellowship Office, National Research Council, 2101 Constitution Ave., N. W., Washington 25, D. C.

FOREIGN

Congress on Anesthesiology.—The World Congress of Anesthesiologists will convene in the Kurhaus at Scheveningen near The Hague (Holland), Sept. 4-10. The subjects of the congress will be (1) the physiological, pharmacological, and clinical aspects of muscle relaxation, hypotension, hypothermia, and artificial hibernation, (2) respiration and circulation, and (3) the teaching of anesthesia.

Symposium on Migraine and Vascular Allergy.—At its second symposium in Basle, Switzerland, July 3-8, the Collegium Internationale Allergologicum had as its main theme "Migraine and Vascular Allergy." The presentations included "Migraine and Other Vascular Headaches" by Dr. Harold G. Wolff, New York, and "Food-Induced Allergic Headaches in Nonmigrainous and Migrainous Individuals" by Dr. William Kaufman, Bridgeport, Conn.

International Pharmaceutical Congress.—The 16th general assembly of the Féderation Internationale Pharmaceutique will convene in London, England, Sept. 19-23. Among the topics for discussion will be: Tests for the Sterility of Pharmaceutical Preparations; Absorption of Medicaments by Various Routes of Administration; Professional Liability and Professional Insurance Against Risks; and Pharmacy of Blood, Blood Products, and Blood Substitutes. The following symposiums have been scheduled: Standardization of Medicinal Plants; Determination of the Active Principles of Drugs and the Unification of Methods of Assay; and Recent Advances in Phytotherapy.

Neuropsychiatric Meetings.—The convention of the German Society of Neurologists and Psychiatrists will be held Sept. 19-22 at the University of Hamburg in Germany. The main subject is the "Motor Apparatus, Its Functions and Mode of Action." A group discussion on "The Training of the Neurologist" is scheduled. On Wednesday at 8 p. m. there will be a session of the Association of German Neurologists. Social events will include opera or the theater, dinner at the Hotel Atlantic, a steamship excursion to Helgoland, excursions through the fort of Hamburg, and visits to various museums. For information write to Dr. Magun, Nervenklinik, Hamburg-Eppendorf, Germany.

Congress on Hematology.—The fifth International Congress of the European Society of Hematologists, organized in cooperation with the German Hematological Society, will be held in Freiburg im Breisgau, Western Germany, Sept. 20-25. Sessions are open to all physicians and scientists interested in hematology. Topics for discussion include: isotopes and cytostatics in hematology; metabolism of iron and copper; neurohumoral regulation of the blood; hepatolienal diseases and their relations to hematology; the heredity of the hemorrhagic diathesis; anticoagulant therapy and prophylaxis of the arterial thrombosis; and hematopoiesis and bone structure. On Sunday there will be a common session on "Biochemistry of the Antibodies" with the Société Internationale de Transfusion Sanguine and the Deutschen Gesellschaft für Bluttransfusionen.

CORRECTION

Urologic Complications of Sickle Cell Disease.—Line 22 in the abstract on sickle cell disease on page 551 of the issue of Feb. 5, 1955, should read: "hormone plays a causal role in the priapism of sickle cell disease," not "a causal role in sickle cell disease."

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

1956 Annual Meeting, Chicago, June 11-15.

1956 Clinical Meeting, Seattle, Nov. 27-30.

1957 Annual Meeting, New York, June 3-7.

American Medical Association Public Relations Institute, Drake Hotel, Chicago, Aug. 31- Sept. 1. Mr. Leo E. Brown, 535 N. Dearborn St., Chicago 10, Director.

American Association of Nursing Homes, Hotel Muehlebach, Kansas City, Mo., Sept. 19-21. Mr. Ira O. Wallace, P.O. Box 366, New Castle, Ky., Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, The Homestead, Hot Springs, Va., Sept. 8-10. Dr. Frank R. Lock, Bowman Gray School of Medicine, Winston-Salem, N. C., Secretary.

American College of Hospital Administrators, Convention Hall, Atlantic City, N. J., Sept. 17-19. Mr. Dean Conley, 620 North Michigan Ave., Chicago 11, Executive Director.

American Congress of Physicial Medicine and Rehabilitation, Hotel Statler, Detroit, Aug. 28-Sept. 2. Dr. Frances Baker, 30 North Michigan Ave., Chicago 2, Secretary.

American Fracture Association, Hotel Fontainebleau, Miami Beach, Fla., Sept. 19-22. Dr. Homer D. Junkin, Paris Hospital, Paris, Ill., Secretary.

American Hospital Association, Traymore Hotel, Atlantic City, N. J., Sept. 19-22. Dr. Edwin L. Crosby, 18 East Division St., Chicago 10, Director.

American Medical Writers' Association, Jefferson Hotel, St. Louis, Sept. 30-Oct. 1. Dr. Harold Swanberg, P.O. Drawer 110, Quincy, Ill., Secretary.

American Physiological Society Fall Meeting, Tufts College, Medford, Mass., Sept. 6-9. Dr. Allan C. Burton, Univ. of Western Ontario, London, Ont., Canada, Secretary.

American Roentgen Ray Society, Palmer House, Chicago, Sept. 20-23. Dr. Barton R. Young, Germantown Hospital, Philadelphia 44, Secretary.

American Society of Plastic and Reconstructive Surgery, Atlantic City, N. J., Sept. 25-30. Dr. Kenneth L. Pickrell, Duke Hospital Durham, N. C., Secretary.

American Veterinary Medical Association, Radisson Hotel and Auditorium, Minneapolis, Aug. 15-18. Dr. J. G. Hardenbergh, 600 South Michigan Blvd., Chicago 5, Executive Secretary.

Biological Photographic Association, Wisconsin Hotel, Milwaukee, Aug. 30-Sept. 2. Miss Jane H. Waters, c/o Pavelle Color, Inc., 533 W. 57th St., New York 19, Executive Secretary.

Clinical Orthopaedic Society, Skirvin Hotel, Oklahoma City, Sept. 30-Oct. 1. Dr. Marcus J. Stewart, 869 Madison Ave., Memphis, Tenn., Executive Secretary.

Colorado State Medical Society, Shirley-Savoy Hotel, Denver, Sept. 20-23. Mr. Harvey T. Sethman, 835 Republic Bldg., Denver 2, Executive Secretary.

Industrial Health Conference, Shamrock Hotel, Houston, Texas, Sept. 22-23. Dr. Sidney Schnur, 411 Medical Arts Bldg., Houston 2, Texas, Chairman.

Kentucky State Medical Association, Louisville, Sept. 27-29. Mr. J. P. Sanford, 620 S. Third St., Louisville, Executive Secretary.

Michigan State Medical Society, Pantlind Hotel, Grand Rapids, Sept. 26-30. Dr. L. Fernald Foster, 606 Townsend St., Lansing 5, Secretary.

Mississippi Valley Medical Society, Jefferson Hotel, St. Louis, Sept. 28-30. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Montana Medical Association, Baxter Hotel, Bozeman, Sept. 15-18. Mr. L. R. Hegland, P.O. Box 1692, Billings, Executive Secretary.

National Medical Association, Los Angeles, Aug. 8-11. Dr. John T. Givens, 1108 Church St., Norfolk 10, Va., General Secretary.

Nevada State Medical Association, Riverside Hotel, Reno, Aug. 18-21. Dr. William A. O'Brien III, 505 Chestnut St., Reno, Secretary.

New England Health Institute, Colby College, Waterville, Me., Aug. 30-Sept. 1. Dr. Edward W. Colby, City of Portland Health Dept., Portland, Me., Chairman.

New Hampshire Medical Society, Mt. Washington Hotel, Bretton Woods, Sept. 29-Oct. 1. Dr. Warren H. Butterfield, 18 School St., Concord, Secretary.

North Texas-Southern Oklahoma Fall Clinical Conference, Wichita Falls, Tex., Sept. 17. Dr. E. C. Bebb, Broad St., Wichita Falls, Tex., Chairman.

Oregon State Medical Society, Hotel Heathman, Portland, Sept. 28-Oct. 1. Dr. Richard R. Carter, 1020 S.W. Taylor St., Portland 5, Secretary.

Pacific Dermatologic Association, Mexico, D. F., Mexico, Aug. 22-24. Dr. Ben A. Newman, 436 N. Roxbury Drive, Beverly Hills, Calif., Secretary.

Pennsylvania, Medical Society of the State of, William Penn Hotel, Pittsburgh, Sept. 18-23. Dr. Harold B. Gardner, 230 State St., Harrisburg, Secretary.

Postgraduate Assembly in Endocrinology and Metabolism, Indianapolis, Sept. 26-Oct. 1. Dr. John J. Mahoney, Assistant Dean, Indiana University School of Medicine, 1040 W. Michigan St., Indianapolis 7.

Regional Meetings, American College of Physicians:

Jamestown, N. D., Sept. 10. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Executive Secretary.

Reno Surgical Society, Reno, Nev., Aug. 18-20. Dr. James R. Herz, 509 Humboldt St., Reno, Nev., Secretary.

Closing date for the October examination was July 1 and for the March examination is December 1. *Part II.* Buffalo, Sept. 26-27; Chicago, Oct. 27-28; New York City, Nov. 14-15; St. Louis, Dec. 12-13; New Orleans, Jan. 16-17; Los Angeles, Feb. 13-14; San Francisco, Feb. 16-17; Durham, Mar. 12-13; Boston, May 14-15 and Philadelphia, June 4-5. Sec., Dr. John B. Flick, 255 S. Fifteenth St., Philadelphia 2.

THE BOARD OF THORACIC SURGERY: *Written.* Various Centers, Sept. 9. Final date for filing applications was July 1. Sec., Dr. Wm. M. Tuttle, 1151 Taylor Ave., Detroit 2.

MAGAZINE-TELEVISION REPORT

The following list of current medical articles in mass-circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of THE JOURNAL. *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported.*

TELEVISION

Monday, August 8

NBC-TV, 9 p. m. EDT. "Medic" presents "The Wild Intruder," a rerun of a story about a young woman who gains courage for a new life after an operation for breast cancer.

Tuesday, August 9

CBS-TV, 10:30 p. m. EDT. "The Search" repeats a program from last season. Filmed at New York University-Bellevue Medical Center, it is titled "Independence for Paraplegics."

MAGAZINES

Ladies' Home Journal, August, 1955

"Babies Should Be Born at Home!" by Dr. M. F. Ashley Montagu

The author presents arguments in favor of having children at home and says: "The family is a unit, and its unity should never be broken. If that unity must be disturbed, it should never be in the manner so mechanically and unnecessarily produced by the usual obstetrical hospital."

Cosmopolitan, August, 1955

"A New Drug Brings Relief for the Tense and Anxious," by Lawrence Galton

"A new drug, Miltown . . . promises quick and safe relief for the tense and anxious. . . . Miltown is the most recent derivative of mephenesin. Not only is it effective, it is also free of penalty. The usual dose is one 400-milligram tablet after each meal and one at bedtime."

Family Weekly Magazine, July 31, 1955

"What's Behind Your Headaches?" by Regina Gruss

"This common complaint is a symptom, not a disease; it may be the harbinger of serious trouble." The article concludes with this advice: "Your general practitioner is well-equipped to tackle the problem. You can help him and yourself by seeing him promptly and cooperating with him fully."

Harper's Magazine, August, 1955

"The Salk Vaccine: What Caused the Mess?" by Leonard Engel

In analyzing what is called "the chaotic confusion over the polio inoculations," the author placed primary blame on governmental agencies. He says, "The Health Service and the Department (of Health, Education and Welfare) not only hurt the polio program and themselves by doing the wrong things. They did it through plainly avoidable public-relations ineptness." In two places Mr. Engel scolds the American Medical Association, together with the National Foundation for Infantile Paralysis and the Public Health Service, for failing to inform the public that vaccine takes some time to produce immunity and for the "notable lack of real planning for the technical aspects of producing vaccine."

Look, August 9, 1955

"Hiroshima Diary," by Dr. Michihiko Hachiya

An account of the Hiroshima atomic bombing through the eyes of a Japanese physician.

Saturday Evening Post, July 30, 1955

"They Heal Heartsick Children," by Jerome Ellison

The story of a nonprofessional volunteer organization called Recreation Service, Children of Bellevue, Inc. Dr. Randolph A. Wyman, Bellevue's medical superintendent, is quoted in the article as saying, "These amateurs are regarded as indispensable members of the hospital staff. We could no more do without them than we could do without penicillin."

DEATHS

rry, Benjamin Taylor ⊕ Rochester, Minn.; born in Birming- m, Ala., June 10, 1876; Johns Hopkins University School of edicine, Baltimore, 1904; research fellow in pathology at the iversity of Chicago, 1904 to 1905; member of the staff of the ockefeller Institute for Medical Research in New York City om 1906 to 1913; director of laboratories at the Kings County ospital in Brooklyn from 1913 to 1918; instructor of pathology Columbia University College of Physicians and Surgeons in ew York City from 1914 to 1918; professor of pathology at e Vanderbilt University School of Medicine and pathologist the Vanderbilt University Hospital in Nashville, Tenn., from 18 to 1925; postgraduate instructor in pathology at the Uni- rsity of North Carolina in the summer of 1923; director of boratories at the Toledo (Ohio) General Hospital, 1925 to 926; from 1926 to 1932 was at the Mayo Clinic as research orker on malignancy; acting professor of pathology at the niversity of Texas School of Medicine in Galveston, 1932 to 33; for many years on the staff of the Tacoma (Wash.) General ospital; specialist certified by the American Board of Pathol- gy; member of the American Association for the Advance- ent of Science and the American Society of Clinical Pa- ologists, which in 1938 awarded him its gold medal for an hibit on "Aids in Rapid Diagnosis of Tissues"; emeritus mem- r of the College of American Pathologists; the American edical Association in 1923 awarded him a Silver medal "for e demonstration of instructive specimens of pathologic an- tomy," in 1924 the Bronze medal, in 1927 a Certificate of erit "for exhibit of new stain and method of tissue micro- copy and excellence of demonstration," in 1928 special men- on "for excellence of personal demonstration," and in 1947 onorable mention "for exhibit on Razor Section Technic and e Polychroming of Methylene Blue"; from 1911 to 1913 joint ditor of *Journal of Experimental Medicine;* died June 14, ged 78.

Camp, Carl Dudley ⊕ Ann Arbor, Mich.; born in South Watauga, Tenn., Oct. 2, 1880; University of Pennsylvania Department of Medicine, Philadelphia, 1902; interned at the Howard Hospital in Philadelphia; from 1904 to 1907 instructor in neurology and neuropathology at his alma mater and assistant neurologist at Philadelphia General, Philadelphia Polyclinic, and University of Pennsylvania hospitals; in 1907 joined the faculty of the University of Michigan Medical School as clinical professor of diseases of the nervous system; in 1920 his title was changed to that of professor of neurology; later became professor emeritus of neurology; member of the American Neurological Association, of which he was formerly vice-president; one of the original members of the Central Neuropsychiatric Association; in 1914 president of the Detroit Neurological Society (now the Michigan Society of Neurology and Psychiatry); member of the Philadelphia Neurological Society, American Association of Pathologists and Bacteriologists, the American Psychopathological Association, the Research Club of the University of Michigan, Nu Sigma Nu, Alpha Omega Alpha, and Sigma Xi; honorary member of the American Academy of Neurology; died in the University Hospital May 23, aged 74, of hemorrhage from the urinary bladder.

Donaldson, Frederick August ⊕ Westwood, Mass.; Harvard Medical School, Boston, 1904; died May 5, aged 86, of arteriosclerotic heart disease.

Douglass, William Tyler ⊕ Harrisburg, Pa.; Jefferson Medical College of Philadelphia, 1901; an associate member of the American Medical Association; fellow of the American College of Surgeons; past-president of the Harrisburg Academy of Medicine and the Dauphin County Medical Society; served on the staff of Harrisburg Polyclinic Hospital; died May 3, aged 81, of coronary occlusion and myocardial infarction.

Duffy, Richard Nixon ⊕ New Bern, N. C.; Johns Hopkins University School of Medicine, Baltimore, 1906; fellow of the American College of Surgeons; on the staff of St. Luke's and Good Shepherd hospitals; died April 14, aged 72, of a heart attack.

Farnacy, Nicholas Lester ⊕ Cleveland; Western Reserve University School of Medicine, Cleveland, 1921; fellow of the American College of Surgeons; life member of the Cleveland Museum of Art; a member of the Cleveland Health Museum; on the staffs of the St. Luke's and Woman's hospitals and the Huron Road Hospital, where he died June 8, aged 59, of cancer.

Fedde, Bernhard Andreas, Brooklyn, N. Y.; University and Bellevue Hospital Medical College, New York City, 1900; member of the Medical Society of the State of New York; at one time assistant clinical professor of medicine at the Long Island College of Medicine; consultant in medicine at Kings County Hospital; physician emeritus at Norwegian Lutheran Deaconess Home and Hospital; died June 14, aged 77, of angina pectoris.

Ferguson, John Angus ⊕ Wyckoff, N. J.; Long Island College Hospital, Brooklyn, 1896; an associate member of the American Medical Association; formerly member of the board of education in Brooklyn; died in Valley Hospital, Ridgewood, June 9, aged 82, of arteriosclerosis.

Finner, Lucy Louise, San Francisco; Rush Medical College, Chicago, 1930; certified by the National Board of Medical Examiners; died in the San Francisco General Hospital May 29, aged 56, of multiple embolism of the lungs.

Flinn, Charles C. ⊕ Allegan, Mich.; Bennett Medical College, Chicago, 1901; died in the Allegan Health Center April 6, aged 78, of uremia.

France, Joseph John, Napa, Calif.; Milwaukee Medical College, 1905; served during World War I; died in the Providence Hospital, Oakland, May 25, aged 78, of acute hemorrhagic pancreatitis.

Frankel, Herbert, Framingham, Mass.; College of Physicians and Surgeons, Boston, 1914; died June 10, aged 66.

Frankenstein, Victor Samuel ⊕ Chicago; Northwestern University Medical School, Chicago, 1895; an associate member of the American Medical Association; on the staff of the Michael Reese Hospital and the Woodlawn Hospital, where he died June 15, aged 85, of acute bacterial endocarditis.

Frost, Charles L., Bolivar, Tenn.; Memphis (Tenn.) Hospital Medical College, 1909; died June 1, aged 72, of coronary occlusion and cirrhosis of the liver.

Gore, Samuel Kirkham ⊕ Houston, Miss. (licensed in Mississippi in 1922); died in the Houston Hospital June 12, aged 68, of carcinoma of the rectum.

Griggs, Samuel Otis, Fort Thomas, Ky.; Medical College of Ohio, Cincinnati, 1896; member of the Kentucky State Medical Association; for many years health officer of Dayton, where he was on the staff of the Speers Memorial Hospital; died April 1, aged 82, of arteriosclerosis.

Haines, Franklin Gregg ⊕ Warren, Pa.; Baltimore Medical College, 1895; for many years county medical director; on the staff of the Warren General Hospital, where he died May 19, aged 83, of chronic cholecystitis and peritonitis.

Hammond, James William, Byron, Calif.; California Medical College, San Francisco, 1897; died in Martinez June 10, aged 98, of arteriosclerosis.

Hayes, Joseph Owens ⊕ Detroit; University of Buffalo School of Medicine, 1947; interned at the Sisters of Charity Hospital in Buffalo; formerly a resident at the Massachusetts Memorial Hospitals in Boston and the Allegheny General Hospital in Pittsburgh; certified by the National Board of Medical Examiners; formerly on the staff of the Veterans Administration Hospital in Buffalo; on the staff of the Jennings Memorial Hospital; died May 27, aged 34, of coronary occlusion.

Hennemuth, John Henry ⊕ Emmanus, Pa.; Jefferson Medical College of Philadelphia, 1922; formerly deputy coroner, councilman, and burgess; past-president of the Lehigh County Medical Society; served in the Mexican Border campaign, World War I, and during World War II; died March 30, aged 59, of coronary occlusion.

Hickman, George Lester ⊕ Bryant, S. D.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; died June 13, aged 75, of cerebral thrombosis.

Hill, George Ray ⊕ Rochelle, Ill.; University of Illinois College of Medicine, Chicago, 1936; interned at the Mercy Hospital in Cedar Rapids, Iowa, and the Methodist Hospital in Fort Wayne, Ind.; served during World War II; died June 11, aged 44.

Hofferkamp, August George ⊕ Jeffersonville, Ind.; Loyola University School of Medicine, Chicago, 1926; member of the American College of Chest Physicians and the American Trudeau Society; died in the St. Edward Hospital, New Albany, March 25, aged 62, of cancer of the pancreas.

Horsley, Frederick Melville ⊕ Arrington, Va.; Medical College of Virginia, Richmond, 1908; served during World War I; died May 11, aged 80, of coronary thrombosis.

Howe, William R., Youngstown, Ohio; College of Physicians and Surgeons, Baltimore, 1899; died in the North Side Hospital June 20, aged 91, of cerebrovascular accident and arteriosclerosis.

Huffman, James William, Bismarck, Mo.; Medical College of Indiana, Indianapolis, 1905; died April 9, aged 77, of hypostatic pneumonia.

Hulbush, William Albert ⊕ Bellingham, Wash.; Indiana University School of Medicine, Indianapolis, 1908; past-president of the Whatcom County Medical Society; formerly chairman of the city health board and county coroner; associated with the state department of public health as screening physician in Whatcom County for public assistance medical services; served during World War I; past chief of staff of St. Luke's Hospital, where he died May 25, aged 70, of coronary disease.

Hunsicker, Hannah Marian, Huntingdon Valley, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1902; public school doctor; died April 8, aged 90, of carcinoma.

Hunter, Edward R. ⊕ Delanco, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1914; an associate member of the American Medical Association; health officer; on the staff of Burlington County Hospital in Mount Holly; died in the Presbyterian Hospital, Philadelphia, June 6, aged 67, of heart disease.

Huntington, Harry Gilbert ⊕ Howell, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1912; for many years city health officer; for 12 years served on the school board; died June 6, aged 70, of acute congestive cardiac failure.

Jahiel, Richard, New York City; Université de Paris Faculté de Médecine, France, 1927; served in the French Army during the early part of World War II; on the staff of the Montefiore Hospital; died June 1, aged 56, of carcinoma of the stomach.

Jordan, Peter Andrew ⊕ Santa Jose, Calif.; Jefferson Medical College of Philadelphia, 1901; specialist certified by the American Board of Otolaryngology; member of the Pacific Coast Oto-Ophthalmological Society; an associate member of the American Medical Association; past-president of the Santa Clara County Medical Society; served during World War I; on the staff of the Santa Clara County Hospital, O'Connor Hospital, and San Jose Hospital; died June 1, aged 84, of a heart attack.

Kautz, William Shaw, Cincinnati; Miami Medical College, Cincinnati, 1905; on the staff of the Jewish Hospital, where he died June 5, aged 75, of coronary artery sclerosis.

Lee, George Herbert ⊕ Denver; Denver and Gross College of Medicine, 1905; an associate member of the American Medical Association; served on the staffs of the St. Anthony, General Rose Memorial, Presbyterian, and Beth Israel hospitals; died May 31, aged 77, of cerebral thrombosis and arteriosclerosis.

Lynch, George Vincent ⊕ Oshkosh, Wis.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1917; fellow of the American College of Surgeons; past-president of the Winnebago County Medical Society; chief of surgery at Mercy Hospital; died in the Jackson Memorial Hospital, Miami, Fla., April 28, aged 68, of septicemia.

McDonald, William Brown, Dixon, Ill.; Hering Medical College, Chicago, 1910; died June 8, aged 90, of arteriosclerotic heart disease.

McNair, Lawrence N. ⊕ Albion, Mich.; Detroit College of Medicine, 1911; during World War I assigned as medical officer to the Student Army Training Corps unit at Albion College; on the staff of the James W. Sheldon Memorial Hospital, where he was president of the medical staff in 1942, secretary of the staff in 1952, and vice-president in 1953, and where he died June 14, aged 68, of extensive posterior coronary infarction and bronchiectasis.

Matthews, John Calvin ⊕ Huntington, W. Va.; North Carolina Medical College, Charlotte, 1913; fellow of the American College of Surgeons; on the staffs of Guthrie Hospital and St. Mary's Hospital, where he died May 31, aged 69, of myocardial infarction.

Newton, Robley Dunglison, Fort Myers Beach, Fla.; Medico-Chirurgical College of Philadelphia, 1896; died in the Lee Memorial Hospital in Fort Myers April 4, aged 84, of shock.

Offenthal, Adolph W. ⊕ New York City; Université Libre de Bruxelles Faculté de Médecine, Belgium, 1913; died April 26, aged 66, of cerebral hemorrhage.

Oginz, Philip ⊕ Brooklyn, N. Y.; Long Island College Hospital, Brooklyn, 1908; associate member of the American Medical Association; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; member of the Brooklyn Gynecological Society; on the staffs of the Beth-El and Kings County hospitals; died April 22, aged 69, of arteriosclerotic rupture of an aortic aneurysm.

Pardee, Charles Arthur, Fort Myers, Fla.; Northwestern University Medical School, Chicago, 1927; interned at the Wesley Memorial Hospital in Chicago; served during World War I; member of the American Academy of General Practice; died April 22, aged 59, of coronary occlusion.

Resnik, Ernest David ⊕ Brooklyn, N. Y.; Long Island College Hospital, Brooklyn, 1922; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; on the staffs of the Caledonian and Maimonides hospitals; on the staff of the Coney Island Hospital from 1922 to 1927; died June 20, aged 58, of carcinoma of the pancreas.

Ridge, Frank Isaac, Kansas City, Mo.; Columbia University College of Physicians and Surgeons, New York, 1910; assistant clinical professor of medicine at the University of Kansas School of Medicine, Kansas City, Kan.; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; on the staffs of St. Luke's and St. Mary's hospitals; died March 24, aged 69, of rupture of esophageal varices and cirrhosis of the liver.

Roberts, John Charles ⊕ Peoria, Ill.; College of Physicians and Surgeons of Chicago, 1887; honorary member of the staff of Proctor Hospital; died June 19, aged 93, of glomerulonephritis and arteriosclerosis.

Ross, Archibald Charles, Albion, Maine; Medical School of Maine, Portland, 1909; local health officer; on the staff of the Thayer Hospital in Waterville; died May 24, aged 73, of coronary thrombosis.

St. Amant, Guy Stanhope ⊕ Gonzales, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1911; member of the American Academy of General Practice; died in Our Lady of the Lake Hospital, Baton Rouge, May 26, aged 71, of mesenteric thrombosis.

Salmon, Leon Trudeau, New Hope, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1898; died in Glen Cove, N. Y., April 6, aged 79, of arteriosclerotic heart disease.

Schiffman, Fredric Chace, Baltimore; University of Pennsylvania School of Medicine, Philadelphia, 1954; intern at the University of Maryland Hospital; died April 6, aged 24.

Schlatmann, Vincent Henry, Plainfield, N. J.; Georgetown University School of Medicine, Washington, D. C., 1928; served during World War II; on the staff of the Veterans Administration Hospital in East Orange; died May 29, aged 51, of coronary thrombosis.

Schulz, Arthur Paul Erich, St. Charles, Mo.; Washington Unisity School of Medicine, St. Louis, 1912; died in St. Joseph's Hospital May 7, aged 73, of carcinoma of the larynx.

Scott, Samuel Avery, Amarillo, Texas; Western Reserve University School of Medicine, Cleveland, 1947; for two years served in the medical reserve corps of the U. S. Army; interned at the Southern Baptist Hospital in New Orleans; served a residency at the Veterans Administration Hospital, John Gaston Hospital, and the Baptist Memorial Hospital, all in Memphis, Tenn.; died in the Northwest Texas Hospital June 18, aged 30, of acute myocarditis and peritonsillar abscess with septicemia.

Shrimpton, Elizabeth Latimer, Syracuse, N. Y.; Syracuse University College of Medicine, 1901; died June 6, aged 79, of senility.

Simmerman, John Walter, Roanoke, Va.; Maryland Medical College, Baltimore, 1911; for many years member of the school board; member of the Medical Society of Virginia; on the staff of the Shenandoah Hospital; died May 25, aged 67, of acute coronary occlusion.

Smith, John William ⊕ Milwaukee; Marquette University School of Medicine, Milwaukee, 1915; member of the American Academy of Dermatology and Syphilology; formerly on the faculty of his alma mater; past-president of the state board of medical examiners; at one time treasurer of the State Medical Society of Wisconsin; died June 19, aged 63, of pulmonary embolism.

Soles, Fred Arthur ⊕ Platteville, Wis.; the Hahnemann Medical College and Hospital, Chicago, 1903; died in Marshfield May 18, aged 81, of coronary thrombosis.

Stamey, James Thomas ⊕ St. Joseph, Mo.; Central Medical College of St. Joseph, 1897; died June 20, aged 82.

Stitt, Richard Marks ⊕ St. Petersburg, Fla.; Duke University School of Medicine, Durham, N. C., 1946; interned at Duke Hospital in Durham, N. C.; served in the U. S. Naval Reserve on Truk Island in the South Pacific from 1947 to 1949; certified by the National Board of Medical Examiners; on the staffs of the Mound Park and St. Anthony's hospitals; died April 13, aged 34, of hypertension.

Stubenrauch, Charles Henry Sr. ⊕ Havana, Ill.; Johns Hopkins University School of Medicine, Baltimore, 1907; died in a Quincy hospital June 21, aged 74, of coronary disease.

Swope, Oscar Clinton ⊕ Kingston, Mass.; Boston University School of Medicine, 1902; for many years chairman of the school committee and first school physician; served on the board of the Jordan Hospital in Plymouth, where he was a member of the board of trustees of the Plymouth Five Cents Savings Bank; died June 3, aged 78.

Terrell, Thomas K. ⊕ Lynchburg, Va.; University of Virginia Department of Medicine, Charlottesville, 1895; died June 4, aged 85, of pyelonephritis and pulmonary tuberculosis.

Thornton, John Thruston ⊕ Charlottesville, Va.; Medical College of Virginia, Richmond, 1902; member of the American Academy of Pediatrics; fellow of the American College of Physicians; died May 30, aged 79, of arteriosclerosis.

Tyson, John Joyner ⊕ Durham, N. C.; Medical College of Virginia, Richmond, 1928; fellow of the American College of Surgeons; assistant professor of hospital administration at Duk University School of Medicine; served on the staffs of variou administration posts; manager of the Veterans Administratio Hospital, where he died May 27, aged 57, of coronary arter disease.

Wahle, George Henry ⊕ Boise, Idaho; Washington Universit School of Medicine, St. Louis, 1919; fellow of the America College of Surgeons; senior member of the American Goit Association; member and past-president of the Southwest Idah Medical Association; member and past-president of the sta St. Alphonsus Hospital; on the staff of St. Luke's Hospital; die June 20, aged 61, of carcinoma.

Wahrer, Carl William, El Dorado, Calif.; Rush Medical Co lege, Chicago, 1902; died May 29, aged 76, of carcinoma of t cecum.

Waligora, Stanley B., Cicero, Ill.; the Hahnemann Medic College and Hospital, Chicago, 1915; died June 13, aged 6 of coronary occlusion.

Wallace, Charles James, Two Harbors, Minn.; University Minnesota College of Medicine and Surgery, Minneapolis, 190 died April 16, aged 81, of carcinoma of the stomach.

Wang, Israel ⊕ Port Chester, N. Y.; Long Island College Ho pital, Brooklyn, 1913; specialist certified by the American Boa of Internal Medicine; emeritus attending physician at the Unit Hospital, where he died April 26, aged 69, of coronary thro bosis.

Ward, Hugh John ⊕ Hazleton, Pa.; Jefferson Medical Colle of Philadelphia, 1944; interned at the Nazareth Hospital Philadelphia; served in the China-Burma-India Theatre duri World War II; served on the staff of the Shamokin (Pa.) Sta Hospital; died June 3, aged 43.

Watson, Nowlin ⊕ Clarksville, Texas; Kentucky School Medicine, Louisville, 1901; veteran of the Spanish-Americ War; for many years city health officer; past-president of t Rotary Club; on the staff of the Red River County Hospit where he died June 8, aged 76, of diabetes mellitus.

Wellman, Clarence Lovejoy, Grove, Okla.; Kansas City (M Medical College, 1901; veteran of World War I; died June aged 77, of coronary occlusion.

Wells, Milo C., Grove, Okla.; University of Louisville (K School of Medicine, 1929; died in St. John's Hospital, Jopl Mo., June 16, aged 55, of coronary occlusion.

Wiebe, Dietrich Vergil ⊕ Sacramento, Calif.; University Kansas School of Medicine, Kansas City, Kan., 1925; intern at the San Joaquin General Hospital in French Camp; a medical officer for the Bureau of Indian affairs; at one time medical missionary in China; served as board member of t Reedley (Calif.) Hospital; died in San Francisco March aged 67, of coronary occlusion.

Wilkerson, Leonard Boyce, Shorter, Ala.; Kentucky Univers Medical Department, Louisville, 1902; died in Montgome April 20, aged 80, of circulatory failure.

Williams, Leonidas ⊕ Lewisburg, W. Va.; University of Virginia Department of Medicine, Charlottesville, 1939; interned at the Wheeling (W. Va.) Hospital; died June 26, aged 46, of acute myocardial infarction.

Wilson, Dilimus Wesley ⊕ Fort Payne, Ala.; Chattanooga (Tenn.) Medical College, 1900; on the staff of the DeKalb County General Hospital; died June 6, aged 83, of hypostatic pneumonia, osteoarthritis, and myocarditis.

Winter, Joseph Augustus, Leonia, N. J.; Marquette University School of Medicine, Milwaukee, 1937; member of the Association for the Study of Internal Secretions; served during World War II; died in the Englewood (N. J.) Hospital June 9, aged 44, of a coronary attack.

Woodall, Percy Hogan, Homewood, Ala.; University of Nashville (Tenn.) Medical Department, 1896; died April 12, aged 80, of arteriosclerotic cardiovascular disease.

FOREIGN LETTERS

AUSTRIA

Acute Leukemia in Adults.—At the meeting of the Society of Physicians in Vienna on March 4, Braunsteiner and Reimer reported on a 73-year-old woman and a 35-year-old man with acute leukemia who obtained complete, long-lasting remissions with 6-mercaptopurine. Therapeutic success in elderly patients with acute leukemia is rare. The smallest adequate dose is recommended as the therapeutic principle.

Animal Experiments Concerning Vagus Death.—At the same meeting Dr. H. Kolder reported on the cause of death in explosive decompression, a form of death for which the term shock death is suggested. The cause is a pressure wave of known amplitude and duration. It can be proved that the pressure wave attacks the thorax and the lung respectively. There damage is done by which receptors in the lung are stimulated; the stimulus then is transmitted by the vagus nerve to the respiratory center and an irreversible cessation of respiration results. The changes in the lung alone do not threaten life, therefore vagotomized animals can survive the exposure to pressure waves. Anesthesia or covering the thorax with rubber foam also prevents this "vagus death."

Etiology of Congenital Cardiac Defects.—At the same meeting Navratil, Wenger, and Kaindl reported on a series of 100 mothers of patients with congenital cardiac defects and 200 mothers of healthy children who served as controls. It was shown that hormonal disturbances of the mother, which particularly affect the function of the ovaries, predispose to congenital cardiac defects. A significantly increased incidence of late menarche, tendency to repeated spontaneous abortion, temporary sterility, and irregular menstruation was observed in the mothers of children with congenital defects. Other factors consisted of multiparity and advanced age of the mother at the time of parturition. Children with congenital cardiac defects have a larger number of siblings than healthy children of the average population do. If hereditary influences might play a part in the origin of congenital cardiac defects, then it seems most likely that a hereditary hormonal weakness is transmitted. The arrest of development could result from the concurrence of the hormonal disturbance of the fetus and that of the mother.

Idiopathic Epilepsy.—At the same meeting Dr. E. Niedermeyer of Innsbruck discussed the question whether today one still is justified in speaking of idiopathic epilepsy. Electroencephalograms show that some forms of epilepsy do not have their origin in cortical lesions but suggest a functional disturbance of the diencephalic apparatus, for which Penfield and Jasper of Montreal have coined the collective term of "centrencephalon." It is suggested that idiopathic epilepsy is primarily a centrencephalic dysfunction. The three most important factors in epilepsy are: (1) predisposition to convulsions, (2) irritative noxae, and (3) a convulsion eliciting factor. The predisposition to convulsions means a dispositional defect of the cerebral protective mechanisms against the tendency to hypersynchronous-epileptogenic discharge of ganglion cells. This predisposition is especially important in idiopathic epilepsy. Irritative noxae are predominant in the symptomatic forms, but the predisposition to convulsion may also be present. With certain reservations the designation "idiopathic-symptomatic" may still be used.

Shock Therapy in Childhood Psychosis.—At the meeting of the Society of Physicians of Vienna on May 13, Hift and Spiel reported the case of a girl who, at the age of 13, had been subjected to electroshock therapy. An endogenous psychosis had been definitely diagnosed, and the severity of the psychosis justified the treatment. The electroshock therapy, which was carried out under constant control of psychological tests, was successful. Subsequent examinations revealed that no irreversible damage had been caused. Thus shock therapy seems to be indicated even in children, in selected cases.

Glycogen Storage in Diabetic Patients.—At the same meeting Dr. A. Beringer said that he determined the glycogen content of the liver of animals with alloxan diabetes after they had been given injections of regular insulin, protamine zinc insulin, insulin with retarded action, and depot insulin. Repeated injections of small quantities of insulin produced a greater deposition of glycogen than did large quantities of insulin. Under the influence of protamine zinc insulin more glycogen was deposited in the liver than was the case with corresponding doses of regular insulin. The insulin with retarded action and depot insulin had an intermediate action in this respect. It could be demonstrated by means of puncture biopsy of the liver that these results are applicable also to diabetes in human beings. Thus, when diabetic patients have complications in which an increased glycogen content of the liver is desirable, treatment with protamine zinc insulin, retarded action insulin, or depot insulin seems preferable to treatment with regular insulin.

BRAZIL

Serial Sections in Uterine Cervical Atypias.—Drs. Alberto Rocha and Lucy Teixeira of the histopathological laboratory of the gynecologic department, Minas Gerais State University, at Belo Horizonte report in *Anais brasileiros de ginecologia* (20:1, 1955) a series of 33,820 sections made from 101 biopsy specimens and 29 amputated cervices. Among the biopsy specimens, 24 were from patients with stage O cancer whose diagnosis was made by means of histopathological examinations of nonserial sections, before the inauguration of the new laboratory. The 24 histological blocks of the biopsy specimens were reexamined by serial sections, which resulted in the finding of two cases already presenting signs of invasion, invalidating their classification as stage O cancer. One of these two patients had been treated by radium and died five years after the diagnosis of cancer was established. The other, who was treated by simple total hysterectomy, was in good condition six years after the diagnosis was established. Review of the 24 specimens revealed O stage cancer in 15 cases; initial invasion in 2; slight atypia in 2; cervicitis in 2; and insufficient material in 3. A review of the 14 biopsy specimens in the whole series that showed simple atypia confirmed this diagnosis in 11 cases; one was classified cancer stage III, 3b; one, cancer stage Ib with suspicion of IIIB; and one had epithelial hypertrophy and cervicitis. After the inauguration of the new laboratory, 10,464 sections were examined from 61 biopsy specimens. The serial sections from 40 of these revealed simple atypia in 2 cases; increasingly atypical epithelium (stage O cancer) in 2; epithelioma in 4; epithelial perforation in 4; regressive changes in 11; insufficient material in 7; acute condyloma in one case; and normal epithelium in 9. Among the 29 cervices removed, 11 showed stage O carcinomas and 18 showed normal epithelium. In only one was a more marked atypia than that disclosed by the previous biopsy found.

Diffuse Scleroderma.—Dr. J. Aguiar Pupo in *Revista do Hospital das clínicas* (10:1, 1955) analyzed a series of 13 cases of diffuse scleroderma. Seven of the 13 patients were female and 6 were male in contrast to the marked predominance of female patients that is considered a rule in this disease. Only one patient was more than 60 years old; two were more than 40; and the rest were under 35. The onset was preceded by Raynaud's phenomenon in four patients and by varying degrees of edema and pains in the joints in nine. Scleroderma of the

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

extremities was seen in all but one. Diffuse abnormal pigmentation was found in four patients and areas of poikiloderma in three. The esophagus was involved in six patients, the heart in three, the lungs in two, and the intestines in three. The radiological study of the skeleton disclosed a diffuse demineralization, while in the extremities osteoporosis was frequently noted, with narrowing of the articular spaces or bone absorption of the last phalanges. Alterations in the nervous system were not found, except in a patient who presented symptoms of psychosis a few days before he died. The basal metabolic rate was determined in seven patients, four presenting increased values. In a patient in whom the basal metabolic rate was increased, the scleroderma began 18 months after thyroidectomy was performed. Alkaline calcium phosphate and inorganic phosphorus levels in the blood were normal in all patients. The globulin level was always increased. Histopathological examinations disclosed the usual changes and frequently the findings of liquefactive degeneration of the basal layer and a variable number of chromatophores full of melanin in the chorion. It was also ascertained that the involvement of the collagenic fibers was not always uniform in the early stages of the process. Thus, in two patients the collagenic tissue of the superficial skin layers was apparently normal, alterations being present only in the deep layers. Fibrinoid degeneration of the collagen or of the vessel walls was not seen. Treatment with cortisone, corticotropin, *p*-aminobenzoic acid, tocopherol, propylthiouracil, pancreatic extract, heparin, and sympathectomy was tried without success. The prognosis of diffuse scleroderma is poor. Death occurred in seven patients after one to five years. The general condition of two patients is not known, but a follow-up of the remaining four indicated that the disease was arrested, although the patients were practically invalids.

Causes of Peritonitis.—Dr. A. Behmer in *Revista do Hospital das Clinicas* (**10**:25, 1955) analyzed 31,000 autopsy reports with the aim of ascertaining the importance of intestinal inflammation as a cause of peritonitis. Peritonitis was classified as caused by nonspecific intestinal inflammations, specific intestinal inflammations, and other causes. There were 582 cases of intestinal inflammation of undetermined cause, but almost all of these presented the pathological features of bacillary dysentery. In this group, 63 cases (10.8%) showed lesions of peritonitis. Intestinal ulcers were the most common, being observed in 337 autopsies, including 245 cases of ulcerative colitis, 44 of ulcerative enteritis, and 48 of ulcerative enterocolitis. Pseudomembranous lesions of the intestines were observed in 150 autopsies, including 93 cases of colitis, 33 of enteritis, and 24 of enterocolitis. The 63 cases of nonspecific intestinal inflammations causing peritonitis involved the small intestine in 26 cases, the colon in 27, and both in 10. There were 50 cases of peritonitis among the 337 autopsies showing intestinal ulcers, or 14.8%, and only 9 among the 150 cases of intestinal pseudomembranous lesions, or 6%. Among the 337 autopsies showing ulcers, the ulcers of the small intestine appeared as the predominant factor in the production of peritonitis, as there were 22 cases of peritonitis among 44 cases of enteritis (50%), while there were only 22 among 245 cases of colitis (9%), and 6 among 48 cases of enterocolitis (12.5%).

A similar study of the group of the pseudomembranous intestinal processes revealed pseudomembranous enteritis in 12.1%, pseudomembranous enterocolitis in 12.5%, and pseudomembranous colitis in only 2.1%. When the ulcers were located in the colon, in a total of 22 cases of peritonitis there were 14 with perforation and 8 without. When the lesion was located in the small intestine, in a total of 22 cases of peritonitis there were 12 with perforation and 10 without perforation. Thus the proportion of cases without perforation is higher in ulcerative enteritis than in ulcerative colitis. In the cases with inflammation of both intestines, in six presenting peritonitis there were two with perforation and four without, such perforations being always observed in the small intestine only. The proportion of peritonitis without perforation is almost the same for the two groups of cases with ulcerative and pseudomembranous inflammation (6 and 6.5% respectively).

In the 31,000 autopsies, there were 1,278 cases of intestinal lesions of a specific character (tuberculosis in 999, amebiasis in 170, typhoid in 41, paracoccidioidomycosis in 36, and venereal lymphogranulomatosis in 32). Of the 1,278 autopsies with specific intestinal lesions, 193 cases (15.1%) were accompanied by peritonitis. The largest number of cases with peritonitis (132) was found in tuberculous group. The second, third, and fourth largest were in the amebiasis, paracoccidioidomycosis, and typhoid groups, with 13.4, 8.8, and 6.7 respectively. Venereal lymphogranulomatosis represented only 2.5% of the cases. If we included tuberculous peritonitis without intestinal lesions we would have a total of 423 cases of peritonitis, 362 being of tuberculous origin, which gives the high proportion of 85.5% of all cases of specific peritonitis. The process that presented the highest proportion of intestinal lesion accompanied by peritonitis was paracoccidioidomycosis with 47.2%, followed, in decreasing order, by typhoid with 31.7%, venereal granulomatosis with 15.6%, amebiasis with 15.2%, and tuberculosis with 13.2%.

Besides the causes of peritonitis in connection with the previous two groups of nonspecific and specific intestinal lesions, there were 792 autopsies presenting peritonitis due to other causes including surgical acts in 259, tumors in 106, appendicitis in 82, diseases of the liver and the biliary ducts in 66, diseases of the genitals in 42, gastric ulcer in 26, duodenal ulcer in 26, megacolon in 18, septicemia in 16, strangulated hernia in 12, myocardial infarction in 6, intestinal obstruction in 5, megaesophagus in 4, less frequent causes in 86, and undetermined causes in 38.

Cancer of the Thyroid.—Cancer of the thyroid is not so rare as was formerly thought, according to Dr. A. Rego in *Revista brasileira de cirurgia* (**29**:31, 1955), who reports a series of 1,231 patients who underwent thyroidectomy for goiter. Of these patients, 56 were found to have cancer. This incidence of cancer varies according to the type of goiter. A higher frequency was observed in nodular goiter (52 cancers in 910 patients) than in toxic diffuse goiter (4 cancers in 321 patients). It is also higher in nontoxic goiter (35 cancers in 470 patients) than in toxic goiter (21 cancers in 761 patients). Among the 910 patients with nodular goiter, the incidence of cancer varied depending on whether the goiter was uninodular or multinodular. In the former there were 39 cancers in 395 patients, and in the latter there were 13 cancers in 515 patients. Dr. Rego found cancer in both toxic and nontoxic goiters, but a higher incidence was discovered in uninodular goiter. Of 470 patients with nodular nontoxic goiter there were 35 cancers, or 7.4%, the incidence for uninodular and multinodular nontoxic goiters being respectively 10.7 and 4.5%, while among 440 patients with toxic goiter there were 17 cancers, or 3.9%, the incidence for uninodular and multinodular toxic goiter being respectively 8.8 and 0.7%. These figures illustrate the markedly higher frequency of cancer in uninodular goiter, be it toxic or nontoxic. These small tumors are precisely the ones that go undetected, or whose surgical removal is generally believed to be contraindicated. They cause little physical inconvenience and small or no functional impairment of the gland, the patient being always grateful to the physician who, erroneously, follows this line of reasoning.

Intestinal Schistosomiasis.—The repeated examination of stools, even by means of the sedimentation technique, will not reveal all cases of intestinal schistosomiasis, because of the small number of schistosomes, or the predominant infestation by parasites of the same sex, or even the advanced stage of the disease. Believing that the epidemiological significance of this fact for the evaluation of the incidence of the disease in endemic areas had never been studied before, Dr. Luis Pereira da Silva and co-workers, of the National Department of Health, made an experimental study in a rural district in the state of Paraíba. An earlier survey of the district showed an infestation index of 8.7% for the age group from birth to 9 years, and 33% for the group 10 years and over. For the present study the authors performed four successive stool examinations and an intradermal test on 67 random persons aged 10 or over who showed negative results on first examination. By this method the incidence of the disease was found to be not 33 but 73%. For other intestinal helminths (Ascaris lumbricoides, Trichuris trichiura, Strongyloides stercoralis, Enterobius vermicularis, and Ancylostoma duodenale) the infestation index went up about 50%. The authors conclude that the results of surveys made through only one stool examination do not represent the real incidence of intestinal schistosomiasis. In areas where the disease has long been endemic, if the stool survey reveals the existence of a certain number of persons harboring the parasite and the exposure of the entire population is about equal, the use of adequate diagnostic procedures will probably disclose that most of the population is parasitized. One of the main causes of variation of the infestation index in different localities is the use of nonhomogeneous groups of persons, when these localities lie in a zone where the disease has long been endemic.

New Maternity Hospital.—The Maternity Hospital of São Paulo, which was officially opened on Mother's Day, is the biggest hospital devoted exclusively to obstetrics in South America. The city of São Paulo, which has 3 million inhabitants, needs about 2,000 obstetric beds and with the addition of 500 beds in the new hospital there are now 1,421 such beds available. An increment of about 200 beds each year is needed for the city. The new hospital can accommodate about 26,400 deliveries a year. The nursery has room for 450 patients, of which 40 cradles are for prematures and 15 are in an isolation ward. There are 16 delivery rooms, 8 of which are equipped for major operations.

CHILE

Correlation of Symptoms with Hemodynamic Findings in Mitral Valve Stenosis.—At a meeting of the Chilean Heart Society in 1954, Prof. F. Rojas and his co-workers stressed the importance of making a correct diagnosis of pure mitral valve stenosis and the degree of stenosis, so that the advisability of surgical treatment could be evaluated. In a series of 30 patients with pure or predominant mitral valve stenosis, the average age was 33 years. Eighteen were treated surgically. Paroxysmal dyspnea, pulmonary edema, and hemoptysis were not seen when the mitral orifice had an area of 1.5 sq. cm., but if the area was smaller one or more of these symptoms was present. There was no clear-cut relation between cardiac output and body development. One-third of the patients had cyanosis and/or the typical mitral facies. Although the oxygen saturation was practically normal in all patients, the difference in oxygen saturation between arteries and veins was great in all patients but was slightly greater in the cyanotic group. The decrease in the vital capacity of the cyanotic group was more striking. The arterial blood pressure was compared with the area of the mitral orifice and the cardiac output, and it was found that as the area decreased the systolic pressure and output also decreased proportionately. In all these patients a definite correlation existed between the clinical and hemodynamic findings. A similar correlation could be established with pulmonary capillary pressure. A relationship also existed between the intensity of the second pulmonic sound and pulmonary pressure. The radiographic study of the left auricle and mitral area and the capillary pressure also revealed a definite correlation. Correlation between the size of the right ventricle and pulmonary arterial pressure on one hand and total pulmonary resistance on the other were also noted, as was right ventricular hypertrophy as shown in the electrocardiograms in relation to pulmonary arterial pressure, arteriolar resistance, and area of the mitral orifice.

CUBA

Gout.—In *Revista médica cubana* (vol. 66, no. 3, March, 1955) Dr. J. M. Ballejo said that gout is almost forgotten in Cuba, because it is considered to originate only in foreign countries. None of his 17 patients with the disease gave a family history of gout. All of his patients were white men. Obesity was present in 10 patients in his series, alcoholism in 13, and hypertension in 4. The average age of the patients was 40 years and the duration of the disease varied from a few weeks to 14 years. The initial attack occurred in the large toes, ankles, or both. An average of 12.2 mg. of 17-ketosteroids per 100 cc. was found in 24-hour urine specimens. The determination of the 17-ketosteroid level was of diagnostic value. The drugs used included colchicine, corticotropin, sodium salicylate, aspirin, probenecid, and cinchophen. Cinchophen, because of its toxic effects, must be used with caution. Patients must rest and have a light purine-poor diet with fruit juice, milk, and plenty of water.

Action of Histamine and Salicylates on Rheumatic Conditions.—In the same issue Landa and de Diego state that, since the effects of cortisone and corticotropin on rheumatic joints has been studied, many observations have been made to determine whether the beneficial results obtained by salicylates were produced by a similar mechanism. They showed that salicylates given orally and parenterally acted similarly to corticotropin; that histamine produced an eosinopenia within 90 minutes of its administration similar to but more rapid than that of the hormones and salicylates; and that patients to whom combined histamine and salicylates were administered by iontophoresis showed the same improvement as when corticotropin was used. In a series of 65 patients, 36 had bursitis, 25 calcific tenontitis of the shoulders, and 4 had other types of bursitis. There were 22 healthy control patients. It was found that the good results obtained with iontophoresis with histamine and salicylates were due to the stimulus that salicylates produced on the anterior lobule of the pituitary. Besides the well-known, classic effects of the former, it caused the latter to liberate corticotropin, which in time stimulated the adrenals to produce cortisone, compound F, and other steroids. Histamine and salicylates when given together by iontophoresis act synergistically, producing better results than when only sodium salicylate is used. Histamine given by iontophoresis acts on the eosinophils in the same way as when it is injected.

DENMARK

Bovine and Human Brucellosis.—In *Danish Medical Bulletin* for May, 1955, Axel Thomsen stated that by 1944 the charting of bovine brucellosis had reached such a point that about 25% of all the herds and 11% of the total cattle population in Denmark were found to be infected. In 1946 Denmark adopted the Bang ring test, a sample of milk instead of a sample of blood being used. This simple test is extremely sensitive and can be applied to all the herds in Denmark every third month. Large parts of Denmark are now completely free of the disease, and it is calculated that only about 1% of all the herds are infected as compared with 25% only a few years ago. As a rule, a new outbreak can be suppressed, before any noteworthy damage has been done, by the removal of a single animal. Two years from now there should be only a few isolated cases left, if any. A similar note of justified optimism is sounded in the same issue by Martin Kristensen, with regard to human brucellosis, who shows that, while in 1944 there were 261 such cases, the corresponding figure for 1954 was 33. He notes that the frequency of brucellosis in Greater Copenhagen has decreased since 1942 on an even larger scale and concludes that the effective combating of infectious abortion by veterinarians will mean freedom from the human infection.

Cancer of the Breast.—In *Ugeskrift for læger* for May 19 Dr. Erik Andersson states that it is a measure of our uncertainty over the merits of hypophysectomy for cancer of the breast that this operation has hitherto been reserved for advanced cases that have proved refractory to more conventional methods of treatment. He reports a series of six patients who suffered from advanced disease with metastases to the bones and soft tissues. They had undergone operative, radiological, and hormone treatment without avail, and the severe pain from which they suffered required large doses of morphine. Their disease had been diagnosed from one to six years earlier, and their ages ranged from 38 to 68 years. They were warned that no cure could be guaranteed them by hypophysectomy, which was preceded and followed by cortisone treatment. All six patients stood the operation well, but in one of them, a woman aged 55, bilateral parotitis and pneumonia developed on the fifth postoperative day. The extensive metastases in the liver may have contributed to her death. Three to four months after the operation the surviving five patients were still free from pain, which had ceased one to three days after the operation. In all of them the sedimentation rate had approached normal levels, and the blood sugar and basal metabolism also showed improvement. Radiological examinations of the metastases showed no regression. The patients felt somewhat tired and their reactions had slowed down slightly, but there was no other psychic change. Their general condition was much improved, and none of them used morphine derivatives as before. Hypophysectomy may achieve a remission if nothing more.

Celiac Disease.—In *Ugeskrift for læger* for April 21 Mette Hertz reports a follow-up study of 31 children treated for celiac disease. Although 2 of them died of this disease and another 2, of fibrosis of the pancreas, 27 of the patients were treated and reexamined from 2½ to 10 years after discharge from hospital when their ages ranged from 4½ to 13 years. None of the patients suffered from severe dyspepsia on reexamination, but 10 were still subject to a slight degree of dyspepsia from time to time. The mental and physical development of the children was so close to normal that it seems justifiable to hope that the acute celiac disease of early childhood will not usually be followed by permanent ill-effects. In the same issue Dr. C. Hansted confirms some of the important observations made by Dicke and his co-workers who have incriminated gluten as being mainly responsible for celiac disease. Hansted has found that gluten from wheat, rye, and oats is detrimental to children suffering from celiac disease and that wheat-starch, corn flour, rice flour, buckwheat, peas, beans, potatoes, various vegetables, meat, and fish are tolerated. Healthy children from 5 months to 10 years old did not react to the administration of gluten, but some infants less than 3 months old reacted to it with dyspeptic symptoms and one of them with increased fat excretion. Hansted's prolonged fat-balance tests have shown that various forms of pure starch are well tolerated by patients with celiac disease, whereas small quantities of flour containing gluten aggravate the fat absorption and clinical manifestations of the disease.

Of What Do Soldiers Die in Peacetime?—In *Ugeskrift for læger* for May 12 Dr. J. B. Dalgaard has investigated the causes of death of 211 soldiers and 97 officers of the Danish Army and Air Force. Serving as controls were the deaths in a normal cross section of the male population of the same age in Denmark. The average age of the officers being much higher than that of the soldiers, it is not surprising to find heart disease, apoplexy, and malignancy figuring more prominently among the former than among the latter, but it is disquieting to note how frequent suicides were among both the military and the control groups. The death rate from this cause among the soldiers was 16% compared with 19% in the controls. Dalgaard has scrutinized the motives for suicide in the military services in the hope of discovering those that can be eliminated by administrative precautions. He has found the conditions of army service responsible for suicide in only three cases, motives of a more personal character being in the overwhelming majority. Broadly speaking, his investigation shows that deaths from natural causes are more rare among soldiers than among civilians, whereas the reverse is the case with regard to accidental deaths due to drowning, explosions, and traffic accidents.

Death of Professor Abrahamsen.—Prof. Harold Abrahamsen, Denmark's leading urologist, was born in 1885. After serving a surgical apprenticeship in many fields he was put in charge of department D of the Bispebjerg Hospital in 1927. This appointment gave him an opportunity to exercise his gifts as a teacher and to develop orthopedic surgery. In 1934 a trip to the United States did much to promote his interest in urology. His 60th birthday was celebrated by the issue of a *Festskrift* containing many articles of general as well as surgical interest. His death on April 20, 1955, was due to cancer of the colon with metastases.

ENGLAND

Rising Cost of Health to the Nation.—At a meeting of the West London Medico-Chirugical Society, Sir John Charles, Chief Medical Officer of the Ministry of Health, stated that the cost of health to the nation has increased steadily since the National Health Service was established. The cost of running the hospitals in the five year period has increased by 32%; salaries of physicians by 27%; salaries of nurses by 37%; and all other salaries and wages by over 47%. Medical staffs have increased by about 18%, nursing staffs by 14%, and administrative staffs by 12%, although there has been hardly any increase in the total number of hospital beds. These were occupied for about 90% of the time, but the turnover has increased from 6.5 to 7.5 patients per bed per year. Hospital inpatients have thus risen from nearly 3 million a year when the Health Service was started to 3,500,000. Delay in filling beds, in starting diagnostic procedures, in starting treatments, and in discharging patients has led to the uneconomic use of beds. Nearly 19,000 general practitioners now attend about 42,400,000 persons, a ratio of 2,330 patients per panel physician. Sir John urged greater economy in prescribing drugs, which cost 88 million dollars annually when the Health Service began but now cost 118 million dollars, an increase of 34%. The most striking changes were in the proportions of mixtures and proprietary preparations. At the beginning of the Service, mixtures accounted for 34% of all prescriptions and proprietary preparations for 16%. Now mixtures have dropped to 24%, and proprietary preparations have risen to 27%. The cost of the pharmaceutical services, 137 million dollars annually, is now nearly as much as the general medical service, which costs 148 million dollars. The number of prescriptions issued a year is 220 million, or over 5 prescriptions a year for every person making use of the Health Service. The average cost per prescription is 60 cents. Sir John believes that some of this prescribing is not strictly necessary. Smaller quantities of drugs could often be prescribed, and some drugs not used could be returned to the pharmacy instead of being thrown away. Antibiotics are probably being abused. At first their use was restricted to the hospitals and treatment was kept under bacteriological surveillance. They are now used indiscriminately when other and less expensive preparations would suffice. It is doubtful that the average proprietary preparation has a greater therapeutic action than the standard one, but there are undoubted exceptions. If the Health Service is to succeed, waste must be eliminated.

Medical Litigation.—A 35-year-old hemophiliac was awarded additional compensation on account of his disability. While driving his van in London he was involved in a minor collision with an ambulance belonging to the London County Council. The accident, which would normally have been trivial, caused bleeding into his hip and knee joints. He was awarded $8,400 special damages and costs. In a normal person the compensation in this case would have been minimal, but the court took the view that liability was not limited to the normal consequences of a negligent act.

Another case concerned a 9-year-old girl who suffered from burns due to an overturned inhaler containing boiling water. She was under treatment for poliomyelitis in a children's ward and had only limited use of her hands and arms. She was given an inhaler containing boiling water for her bronchitis. This was placed on a tray resting on a pillow over her knees. The inhaler was satisfactorily used for two months in this fashion without mishap. One morning when the nurse left the ward for a few moments the inhaler was upset and the child was scalded. Her mother brought an action for negligence against the hospital. The judge held that neither the nurse nor the hospital administration was negligent, since the positioning of the inhaler and the child had been satisfactory. The nurse was responsible for the care of 16 other children. This opinion was upheld in the Court of Appeal.

A patient complaining of pains in the chest went to a hospital in Liverpool. The physician, who was an intern, gave him two tablets of codeine and told him to return later for radiological examination. A quarter of an hour later the patient was found dead near the hospital, death subsequently found to be due to coronary thrombosis. The patient's widow brought an action for damages against the physician and the hospital. The fact that the intern spent an hour examining the patient showed that, although he made a mistake in diagnosis, he was not negligent. After hearing medical witnesses the judge said that the intern was not negligent in rejecting coronary thrombosis as a diagnosis and therefore was not negligent in sending the patient home. The judge added that even if rest had prolonged the patient's life the prognosis would still have been poor and the patient's future as a breadwinner would not have been bright.

Induced Hypothermia.—On April 1 the Section of Anesthetics of the Royal Society of Medicine debated the present status of induced hypothermia. Dr. C. F. Scurr of London said that hypothermia reduced cell metabolism in a linear fashion so that cells could survive anoxia for longer periods. The circulation of the brain in an animal at a temperature of 77 F (25 C) could be completely occluded for 20 minutes without physiological or histological damage to the brain. Recently a case had been reported of a complete circulatory arrest in a child for 22 minutes at a temperature of 71 F in whom there was no evidence of cerebral damage 30 hours after operation. The hypothermic technique is valuable for intracardiac operations requiring an open heart, temporary occlusion of the venae cavae, and cessation of the circulation; for operations in certain congenital cardiac anomalies in which there is cyanosis or the great vessels need transplantation; in cranial operations involving the temporary arrest of part of the circulation of the brain; in certain neurosurgical procedures; and in operations on the great vessels supplying vital organs. Under normal circumstances the kidneys and spinal cord withstand barely 30 minutes of ischemia, but under induced hypothermia at 80.6 to 82.4 F (27-28 C) up to two hours is tolerated. The advantages to be gained from the technique include (1) reduction of the oxygen requirements of the tissues, since if shivering is prevented oxygen consumption falls; (2) reduction of cardiac work; (3) increase in the coagulation time of the blood, which may be beneficial where thrombosis is a hazard; (4) decrease in the amount of anesthetic needed; and (5) reduction of bacterial and enzyme activity.

There are, however, disadvantages such as the increased irritability of the myocardium, which might cause spontaneous ventricular fibrillation. Because of this, continuous electrocardiographic control is essential, as the appearance of arrhythmias or ectopic foci is a danger signal. The exact cause of fibrillation is not fully understood. A possible explanation is that during hypothermia the formation of acetylcholine is depressed, so that the pacemaker loses its dominance and ectopic foci appear. This explains the beneficial effect of neostigmine in preventing ventricular fibrillation. Hyperventilation, with carbon dioxide absorption, helps to reduce the incidence of cardiac irregularities during hypothermia. Other disadvantages are a shift to the left in the oxyhemoglobin dissociation curve, retardation in the elimination of anesthetic agents, production of the stress response to cold, and increased viscosity of the blood. During rewarming, "after-cooling" may occur owing to the opening up of the peripheral circulation with the transfer of very cold blood to the main circulation. A further fall in the central temperature from this cause may lead to ventricular fibrillation.

Dr. Scurr uses a cooling blanket to lower the temperature of the body. The patient is anesthetized with ether, cyclopropane, or thiopentone-nitrous oxide-oxygen and a muscle relaxant to prevent shivering. The body is then wrapped in a blanket through which water circulates at 35.6 to 39.2 F (2-4 C). Before the desired temperature is reached, warm water is circulated through the blanket to prevent the body temperature from falling any further after the cooling process ceases.

Dr. Cecil Gray of Liverpool described his results with induced hypothermia in 110 patients. In the first 40 patients the French technique, with the use of intermittent doses of chlorpromazine, pethidine, and promethazine, was employed, but this has been abandoned because of the long time needed to lower the temperature and the difficulty in controlling shivering. He now induces light anesthesia with thiopentone sodium, nitrous oxide, and oxygen, prevents shivering with *d*-tubocurarine, and aids cooling with moderate doses of chlorpromazine. The body is cooled with ice bags or a cooling blanket. The patient's position is changed every 15 minutes to prevent pooling of blood and "after-cooling" that commonly occurs in patients with a large surface area. Adequate cooling for one and a half hours can be obtained. Dr. Gray induces hypothermia for intrathoracic, neurosurgical, and general surgical operations. In neurosurgery it may be used for long periods with the patient in the upright position; in general surgery a low temperature protects against the effects of surgical trauma, particularly in poor-risk patients. There were 13 deaths in 110 patients, most of whom were poor surgical risks, but 3 were due to pulmonary embolus. Dr. Gray does not believe that cooling is necessary in patients with congenital heart disease undergoing a Blalock's anastomosis, and investigation of his patients undergoing hypothermia did not confirm the view that pituitary-adrenal responses were modified by cold. On the other hand an investigation in dogs suggested that inhibition of the stress response might account for some of the benefits of hypothermia. Hypothermia is a special technique, with definite risks, and should only be used in specially equipped centers.

Who Pays?—A resident on the lonely Scottish island of Ailsa Craig urgently needed medical attention, and on two occasions the local lifeboat was hired to take him to a physician on the mainland. The Ayrshire Medical Executive Council, under the National Health Scheme, met the expense of $45 out of the physician's local mileage fund on the grounds that if the patient had not come to the physician the latter would have gone to the patient, and an arrangement was made to hire the lifeboat in emergencies and pay for it out of the mileage fund for Ayrshire. The Department of Health for Scotland, however, confirmed the view of its auditors that there was no provision under the National Health Service Act to pay the cost of transporting a patient to a physician and, since the patient had not attended a hospital, the cost could not be charged to the ambulance service. The department suggested that the patient should be asked to pay, but this was ignored. Accordingly the department recommended that the local medical committee be asked to agree to the money being paid out of the mileage fund for Ayrshire. The committee, however, refused to accept this proposal, and the executive council has now, at the suggestion of the Department of Health, made application for the amount to be made a first charge on the mileage fund for Scotland.

Training of Nurses.—Owing to the lack of recruitment in the nursing profession, the Scottish Standing Nursing and Midwifery Committee has suggested an experimental two year course and a three year comprehensive course (Work of Nurses in Hospital Wards, London, Her Majesty's Stationery Office, 1955). The two year course might be tried for five years to assess its value. Student nurses would live in a building apart from the hospital, where they would receive their theoretical training and enjoy a corporate life like a resident university student. Ward training would be received in appropriate hospitals nearby. The nearest approach to this at present is the nurses' home attached to some of the larger hospitals. Student nurses should be carefully selected, should have attained a good educational standard, and should not be less than 18½ years old. In any one center the intake should not exceed more than 30 students a year, and to this number there should be allotted three nurse tutors and two clinical instructors. The latter represent a suggested new grade, with a status of ward-nurse with some experience in teaching. The curriculum should include medical, surgical, gynecologic, psychiatric, pediatric, ophthalmologic, dermatological, otorhinolaryngolical, obstetric, infectious disease (including tuberculosis), operating room, and domiciliary nursing. At the moment teaching is rather haphazard and disconnected; if a nurse is busy or on night duty, she may miss important lectures or demonstrations.

A three year course, the same length as the present one, conducted in a hospital or group of hospitals already training nurses is also suggested. Student nurses would obtain experience in general and specialized nursing fields. This plan would give the student nurse experience in those branches she would not normally encounter in general training, such as mental disease, infectious disease, and tuberculosis. Another recommendation is to try the team system, whereby the patients are divided into groups of 10 or 12, and each group assigned to the care of a small team of nurses, comprising a staff nurse, a nurse in training, and a nursing auxiliary. At the moment twice this number are often cared for by only two nurses by day and one at night. The assignment of a group of patients to such a team has already been tried in some hospitals. The objection is that at off-duty times there are no nurses for a particular group of patients and a relief team has to take over. This calls for a larger supply of nurses than exists at the moment.

Scotland's Health in 1954.—In 1954 there were fewer deaths in childbirth and from tuberculosis than ever previously recorded and a continued lowering of the death rate among children under 5 years of age. The incidence of sickness as measured by attendances at hospitals and visits to physicians is, however, still high. There were more than 2 million new hospital outpatients during the year, with total outpatient attendances reaching nearly 7 million and inpatients numbering 500,000. These figures are for a population of about 5,500,000. There was a rise in the death rate of men aged 50 to 64. In the age group 55 to 65, deaths from respiratory cancer were six times as common as two decades ago, and coronary thrombosis was six and one-half times as common. Bronchitis increased by nearly 25%. These figures are for males. The death rate among females of all ages was lower than two decades ago.

Hospital accommodations and hospital staffs have been increased to cope with the call on the health services by the public. By the end of 1954 beds had increased by 9% compared with figures at the beginning of the National Health Service, and the number of nurses rose from 19,000 to 24,000. There was also a rise in the number of hospital specialists. Running costs of the hospital and specialist services in Scotland increased from 69 million dollars in 1949-1950 to $84,500,000 in 1953-1954. These figures were small in comparison with the increased hospital attendances.

The birth rate, 180 per 1,000 population, was higher than it has been for four years. Infant mortality was 31 per 1,000 births and was the same as in 1953, the lowest on record. The stillbirth rate, 25 per 1,000, was also the same as in 1953. The death rate of 12 per 1,000 population was 0.3 below the average of the previous five years. The number of deaths from the principal epidemic diseases was 254, which was 133 fewer than in the previous year.

Factors Affecting Infant Mortality.—The Social Medicine Research Unit of the Medical Research Council and the General Register Office of London have made a joint inquiry into some of the social and biological factors affecting infant mortality in Britain (*Lancet* 1:341; 395, 1955), which is still high. The number of stillbirths last year was nearly 16,000; deaths in the first week of life numbered about 10,000; and the postneonatal mortality was 8,000. The total of 34,000 deaths was 6% of all deaths, but because they occurred at the beginning of life they represent more than 6% of the total wastage of life caused by untimely deaths. Heady and his co-workers, investigating stillbirths and infant deaths for 1949 and 1950 in England and Wales, found that the stillbirth rate rose with age for mothers of any given parity, but the postneonatal death rate decreased with the age of the mother up to 35 years. The stillbirth rate of infants of mothers of a given age was high for the first-born, fell for the second-born and third-born, and rose thereafter. The postneonatal death rate for infants of mothers of a given age, on the other hand, rose steadily with increasing parity. The neonatal death rate varied less than the other two rates and occupied an intermediate position.

These rates were the same in all social classes. Since large families are associated with a relatively high postneonatal death rate, and since families have decreased in size and the postneonatal death rate has fallen from 91 per 1,000 in 1906 to less than 10 today, it is natural to inquire whether the reduction in family size accounts for an important part of the fall in the rate. Figures collected by the Social Medicine Research Unit workers show that change in family size by itself has only made a small contribution to the postneonatal death rate. The fall must be attributed mainly to increased knowledge by mother and doctor of infant care. The strong relationship that emerges from this survey between maternal age and parity and the postneon death rate is of interest. It is well known that age and parity related to the stillbirth rate. This is not surprising, since th factors are related, and possible connections between the ternal, placental, and fetal pathology may be envisaged. relation between age and parity and later mortality does follow so closely from these considerations. It is more inter ing, therefore, that these factors do not affect postneon mortality and that the effect is so different. Stillbirths and p neonatal deaths thus appear to have different causes and q distinct variations with age and parity. Postneonatal deaths due mainly to infections, and as might be expected the de from infection are related to the mother's age and parity much the same way as the total deaths at this age are. Th trends of postneonatal deaths with age, parity, and social c may furnish clews to the spread and control of these infecti Three possible explanations present themselves: increased portunity for infection in a large family; economic conseque of a large family; and the ability or inability of young mot with large families to cope with their babies. At least t vulnerable groups appear from the data of the survey: mot over 35 bearing first babies have a high risk of stillbirth; mot over 40 of any parity have a high risk of stillbirth; and ba of young mothers with large families for their age have a risk of death in the postneonatal period.

Treatment of Service Personnel on Leave.—It has been ag between the health departments and the service departme in consultation with the representatives of the medical pro sion, to allow under certain circumstances service personne leave and those temporarily away from their units to use National Health Service for treatment after April 1. Form they were debarred from free treatment by general practitio under the National Health Service. Service men and wo who are living temporarily away from barracks or other ser establishments and are more than 2 miles from the nearest s ice hospital or medical unit can now seek medical treatm from civilian physicians within the framework of the Nati Health Service as temporary residents, just as a civilian do when away from home. When service personnel are a for over three months from service medical facilities, it be necessary for civilian physicians to accept them on their manent free patient lists. When they are accepted by physicians for treatment they are entitled to receive drugs appliances free. They will pay 14 cents per prescription like general public, but they will be able to reclaim this from t service medical unit. It has also been agreed that, if under tain circumstances drugs and appliances are not obtaine service medical units, they may be obtained through civ physicians under contract with the National Health Service. this purpose special prescription forms will be issued and be recognized by chemists dispensing under the National He Service. General practitioners treating service personnel u the National Health Service will be paid 74 cents if the pat attends the office, $1.40 for a day visit, and $2.10 for a n visit. In addition, the practitioner will be able to claim 14 c a mile each way in excess of 2 miles for his automobile.

Needle Broken During Injection.—A Scottish Court of Ses has ordered a retrial of a case in which a Scottish woman s a physician for damages because he left a broken needle in body (*Scotsman*, Feb. 5, 1955). At the original trial the wo stated that the physician negligently allowed a needle to br when giving her an injection and that the needle was never covered in spite of several operations. The patient's cou argued that the needle used was not strong enough and the physician should have known this. The plaintiff sued $7,000 damages. For the physician's defense it was not den that the needle broke and it was claimed that the correct t of needle was used. It broke on withdrawal, an accident t was not uncommon and reflected no lack of care or skill the part of the operator. The jury rejected the patient's cl and found the physician not guilty of negligence. The pati appealed against the court's findings, claiming that the ju had misdirected the jury. The judge had stated to the jury his summing up that for the claim to succeed there must be such a departure from the normal and usual medical practice as could reasonably be described as gross negligence. The Court of Session has held that the judge's direction did not accurately describe the legal criterion for liability, that therefore the jury's verdict was void, necessitating another trial, that, in order to prove negligence, whether by a physician or anyone else, it was essential to prove a breach of the duty to take the care that the law required, and that lack of care amounting to negligence will vary with the circumstances. Where the conduct of a professional man is concerned the circumstances are not so clear-cut as in most cases seen in the courts. There is ample opportunity for difference of medical opinion in diagnosis and treatment, and a man is not necessarily negligent because he differs from his professional brethren or because he exhibits less skill and knowledge than others might have done. The true test of negligence in diagnosis or treatment is whether the physician is proved guilty of such failure as no physician of ordinary skill would be guilty of if acting with ordinary care.

Health of Young Children in Britain.—In the last 10 years there have been several child health surveys. The latest survey was carried out under the auspices of the University of London, the Society of Medical Officers of Health, and the Population Investigation Committee. This nationwide survey was based on a study of 5,386 children born in the first week of March, 1946, and is to continue until the children are 12 years old. The present report gives the findings relating to the first five years of life of these children. Some confirm what would be expected, namely, that low social class, high parity of the mother, and premature birth have a detrimental influence on the health of young children. Families of four or more children become progressively fewer in passing from the lowest to the highest social group. The children born later into the family tend to be heavier at birth than those born earlier, but by the age of 2 years they weigh less and are shorter and continue to be so up to the age of 4 years. A comparatively high proportion of underweight children are the later born members of large families. Parents belonging to the lower social groups thus produce a greater number of stunted and underweight children and fewer well-developed ones than those of the upper social groups. The reasons for this are not obvious, but undoubtedly nutritional and possibly genetic factors play a part.

Children in large families and lower social groups suffer more from infectious illnesses early in life. The most important factor here is overcrowding. Thus respiratory infections in the children of manual workers are 1.5 times as frequent in houses with two or more persons to a room as in those with one person to one or more rooms. This is borne out by the greater admission rate for respiratory infections in hospitals in Scotland, where there is more overcrowding than in England. On an average, by the age of 5 years 20% of children have been admitted to hospital at least once; later-born children are admitted more often than first-born. The accident rate is not affected by social class or by the size of the family, although it would be expected that accidents would be more likely to occur in poor homes and in large families, with consequent overcrowding and less individual care for each child.

About a quarter of the mothers in the families covered by the survey are working outside the home. This provides an opportunity to study the opposing influences of increased family income and diminished maternal care. There is no evidence that the health of the children of mothers who work outside the home is in any way inferior to that of mothers who stay at home. There is a greater incidence of infection in the very young children of mothers in the first group, but this may be due to crowding in day nurseries. The psychological trauma, if any, produced by early separation of mother and child when the mother goes to work was not investigated. The survey has confirmed the general impression that it is the most careful and conscientious mothers, and those who need advice least, who use the child welfare clinics, rather than the mothers of large families. In all social strata it is the first-born who is taken more frequently to the clinic; the children of large families are less likely to be taken. The latter do not get regular medical supervision until they reach school age. There may be good reasons for this. The mother of a large family has less time to spare to take her children to clinics, and she may believe that experience has made her competent to deal with the younger members of the family herself. It may be that with increase in the size of the family less care is given to the youngest. The fact that 80% of the first-born and only 50% of the youngest children of large families had been immunized against diphtheria suggests that less care is given to the children of large families. The survey showed that 11% of the mothers gave their children fair or poor care, and they were in the poorest and most overcrowded families with many children.

Clinical Trials on Children.—Mr. T. S. Swingler, Member of Parliament, told the House that newborn babies at Bristol Maternity Hospital were given penicillin, not because they needed it but merely as an experiment. He said that some people allowed their enthusiasm for science to override all moral considerations, and he asked the Minister of Health whether he would make sure that, before further clinical experiments on children were undertaken, the nature of such experiments be reported to his department, so that his medical staff could see that there were adequate safeguards against harmful effects. Mr. Swingler further asked whether the Minister would direct hospital management committees on the ethical principles that should govern the conduct of clinical experiments, with particular reference to the importance of securing the consent of the patient or his legal guardian. The Minister, refusing to ban these experiments on children, said that, if a child of his of any age were in hospital and he was told by people of standing that they were interested in knowing the effects of a perfectly safe clinical investigation and, if it might be that they could learn more and drive still lower the infant mortality in this country, he would be delighted to give his consent. He added that the experiments at Bristol were made under the supervision of the professor of medicine and child health, who had declared them to be perfectly safe.

Other members of Parliament disagreed with the Minister and asked for a directive, but he refused to interfere in what was essentially a matter of professional ethics. Mr. Swingler then urged him to ask the British Medical Association and the Medical Research Council to issue a code of ethics. The Minister replied that he might informally draw the attention of these bodies to the matter if he found it necessary, but both the Minister and members of Parliament were agreed that parents should give their consent to clinical trials on children. One member objected that in the Bristol case this was not obtained, and the Minister agreed that this should have been done.

Report on Britain's Health.—The Registrar General's Report on Britain's Health in 1951 (Registrar General's Statistical Review of England and Wales for 1951, London, Her Majesty's Stationery Office, 1955) shows that by 1951 the birth rate had settled to a level above that in the economic depression of the 1930's. There were 1,060 boys born to every 1,000 girls. The decline in infant mortality and the increase in male survival has resulted in a steady rise in the proportion of men to women over the last 30 years. An increase in the marriage rate resulted, the proportion of married women in the age group 15 to 19 years being 83% above the corresponding figure for 1938. Women are not only more likely to marry now but also they tend to marry younger. The influenza epidemic, which was worst in northern England, accounted for a number of deaths. The disease was so widespread that 647,000 sickness claims were made to the Ministry of National Insurance giving influenza as the cause of absence. This was in a working population of about 22 million people. Deaths from influenza were 8% above those from this cause in 1950. Liverpool had its highest weekly death roll since the cholera epidemic of 1849. The steady fall in mortality, which has been going on since the end of the war, received a check. Infant mortality (30 deaths per 1,000 live births) was the same as in 1950.

In 1951 the number of cases of dysentery, whooping cough, and measles was exceptionally high, but poliomyelitis and diphtheria showed a decline. Food poisoning was reported most often in rural districts and in the larger cities. Except for people over 65 years of age, death rates from tuberculosis fell precipitously; yet the number of reported cases, particularly in the age group

15 to 25 years, were higher than before the war. Some of this increase is accounted for by the large number of minimal tuberculous chest lesions found by miniature mass radiography, as well as by more intensive case finding resulting from the careful follow-up of contacts with tuberculous patients. The mortality and morbidity from tuberculosis in Newcastle, Liverpool, and in the industrial cities of the West Midlands and Wales is still excessive. Bronchitis and cancer of the lungs are more common in Liverpool and the West Midlands, while coronary thrombosis and hypertension are, in general, commoner causes of death in urban than in rural districts. Coronary disease and cancer of the lung continue to rise alarmingly. Cancer of the prostate has declined in men below the age of 64, but for other types of cancer death rates by age groups show little change, except cancer of the breast, the mortality from which shows an increase. Death rates from cancer of the uterus have ceased to fall. The death rate from leukemia among children shows a rise, probably because of improved and hence more frequent diagnosis. It is disquieting to find a rise in the mortality in children under 5 years of age from the accidental swallowing of potentially toxic drugs.

Supplementary Estimates for National Health Service.—This year, for the first time since 1949, the government has asked a supplementary estimate from the Treasury to meet the ary expenses of the National Health Service. For England Wales a further $13,574,400 was asked, and $3,452,400 for Scotland. This sum is to eke out the original estimate of $1,212,400,000 for the current fiscal year. The supplementary estimates would have been larger but for the expected savings of $8,400,000 scattered in small sums under many subheadings. The greatest of these expected savings is $3,385,200 on the hospitals and $1,906,800 on civil defense. The extra expenditure is required mostly for salaries of hospital personnel and for the increased price of goods. There has also been a rise in the cost of the pharmaceutical and dental services. The pharmaceutical services in the whole country account for a further $6,672,400 and the dental services a further $5,322,800. The rise in the cost of the pharmaceutical services is attributed to an increase in the number and average cost of prescriptions, though in England and Wales this has been partly offset by the revised arrangements for pricing prescriptions and paying pharmacists. The rise e cost of the dental services is due to an increasing de- for dental treatment in Britain (Supplementary Estimates, Estimates, and Estimates for Revenue Department, London, er Majesty's Stationery Office).

Specialists and the Health Service.—At a meeting of the Joint Consultants Committee, held at the Royal College of Physicians in January, concern was expressed over the lack of balance between the number of posts open to specialists and the number of residents in training. There appears to be a need for improved planning of the specialist services of the country. One of the pressing needs is for suitable quarters for married residents. The committee stressed the desirability of extending arrangements for the consultant domiciliary service, whereby the patient can be seen by a specialist in his or her own home free under the Health Service, to patients in private hospitals. The attention of the Ministry of Health was drawn to the hardship inflicted on patients of modest means who entered such hospitals for domestic reasons or because of lack of adequate accommodation in hospitals under the Health Service and were thereby deprived of the benefit of free specialist advice. Although the Ministry is considering this proposal, its first reaction was that the obligation to provide a domiciliary specialist service is specifically limited to the patient's home.

Cost of Health Services.—It is estimated that in 1955-1956 an extra $67,631,000 will be spent on the Health Service in Britain, making a total annual expenditure of $1,506,286,400, compared with $1,432,865,837 for the previous year (Civil Estimates for the Year Ending March 31, 1956, London, Her Majesty's Stationery Office). Estimated expenditure under most divisions shows an increase. These estimates make no provision for the hospital building program announced earlier this year, expenditure on which is expected to amount to 21 million dollars in 1957-1958. Payments to general practitioners will amount to only 154 million dollars of the 1.5 billion dollar total, or about 10%. Part of the cost of the Service will be offset by patients' payments of 14 cents per prescription. The gross cost of dental treatment (100 million dollars) is below the peak it reached in the early years of the service. The cost of the pharmaceutical service is 154 million dollars. The rise in the estimated cost reflects a bigger demand by the public for the Health Service rather than a rise in the cost of providing the service. The increased payments to hospitals are largely accounted for by higher salaries and maintenance. A recent increase in the salaries of nurses accounts for another 11,200,000 dollars a year. As there are 8,000 more nurses than a year ago, this will also increase the expenditure on the nursing services.

FINLAND

Thrombosis of the Lower Limbs.—On the initiative of *Nordisk medicin* several physicians in Denmark, Finland, Norway, and Sweden have pooled their experiences with thrombosis of the lower limbs. Dr. Otto Wegelius of Helsinki in the May 12 issue states that heart disease is a common precursor of thrombosis, for it was present in 79 of 178 such cases. Other diseases frequently associated with thrombosis and presumably favoring it are polycythemia vera, hypochromic anemia, pernicious anemia undergoing a remission, lymphocytic leukemia, myelocytic leukemia, thromboangiitis obliterans, infectious diseases, and malignant tumors. With regard to the last named, Wegelius recalls that thrombosis in one leg may be the first manifestation of malignant disease elsewhere in the body. At the Maria Hospital, prothrombin determinations of the blood have been made according to two methods, Lehmann's modification of Quick's method being used up to 1951 and Owren's method thereafter. The latter seems to give the better results, for with the Lehmann-Quick method applied to Dicumarol treatment in 122 patients, the embolism frequency among the survivors was 5.7% and the mortality 1.6%. The corresponding percentages for the 108 patients examined by the Owren method were 0 and 1.8 respectively. With regard to the optimal dose of Dicumarol, Wegelius found that it varies with each patient but that, as soon as it has been determined, the prothrombin percentage need be controlled only once or twice a week.

Zilliacus, also of Helsinki, reports a thrombosis rate of less than 1% in more than 8,000 maternity cases yearly. He has learned to dread thromboses when gestation is complicated by myoma or a toxicosis of pregnancy. The patient with myoma for whom cesarean section is indicated appears to be particularly prone to thrombosis. In most cases characterized by obstetric thromboses the thromboses are small and limited to the pelvis. Their existence is suspected when confinement is followed by several days of a rapid pulse and subfebrile temperature resistant to all forms of treatment with the exception of anticoagulants.

Chlorosis.—In *Nordisk medicin* for April, 1955, Brummer and Levanto report five patients with chlorosis treated in the course of three months. It is almost with an apologetic air that so demoded an ailment is discussed in a medical publication. The authors explain the apparent rarity of chlorosis by assuming that many of the patients formerly given this diagnosis are now considered to have pulmonary tuberculosis, bacterial endocarditis, rheumatic fever, and the like. They regard chlorosis not as a disease in a class by itself but as an essential hypochromic anemia of puberty, a contributory factor being an increased need for iron at this age. The healthier lives led by the present generation may partly account for the rarity of chlorosis in modern times.

Prevention and Treatment of Cholelithiasis.—Internists have been inclined to regard the treatment of cholelithiasis almost exclusively as a surgical matter according to Erik Adlercreutz in *Nordisk medicin* for May 12, 1955. Early recognition, however, may lead to effective prevention. With this object in mind the author has scrutinized the records of 192 patients with cholecystitis (163 women and 29 men) treated in his private practice. The records showed that the cholelithiasis had in many patients been preceded by certain conditions or diseases that are forerunners of gallstones. Among his 163 female patients there was a history of gynecologic diseases in 90, of infections of the urinary tract in 85, of periocular hyperpigmentation in 90, of headache in 93, of rheumatic pains in the neck, right shoulder, and arm in 58, of dyspepsia in 125, and of heart disease in 45. In 10 patients as many as 6 of these forerunners of cholelithiasis figured in the same records, but in 75 the number of forerunners was 3 or less.

ISRAEL

Iron Deficiency Anemia.—At the 18th meeting of the Israel Medical Association several papers dealt with iron deficiency anemia. De Vries and Izak reported that they estimated the hemosiderin content in sections of bone marrow obtained by aspiration biopsy from 8 normal control patients and 39 patients with various hematological disorders. In hypochromic anemia due to iron deficiency the hemosiderin content was low, but in macrocytic anemia with normal mean corpuscular hemoglobin concentration and in hemolytic anemia it was excessive. Hemosiderin must be considered as a dynamic form of stored iron, readily releasing iron when required for the production of hemoglobin. Even in severe iron deficiency anemia small amounts of hemosiderin may be present in the bone marrow. In iron deficiency anemia iron may be deposited in the bone marrow as hemosiderin following iron administration before the hypochromia is corrected. When iron is being utilized for hemoglobin production, a marked drop in bone marrow hemosiderin can be demonstrated within 24 hours. Excessive amounts of bone marrow hemosiderin may be associated with abnormal amounts of iron in the body.

Y. Matoth and M. Aschner reported a series of 168 children with anemia of which 94 cases were due to iron deficiency. Iron deficiency anemia constituted 69% of all cases of anemia, excluding hemolytic disease of the newborn, in the age group from birth to 3 years. Undernutrition was prominent among etiological factors contributing to the production of iron deficiency anemia. Sixty-eight per cent of patients with iron deficiency weighed 30% or more below the average for their age; 65% gave definite histories of diets deficient in iron, whereas in 41% a history of recurrent infection, chiefly diarrhea, was obtained. The percentage of children born to mothers who had had six or more previous deliveries was 27 and that of premature infants and twins was 22.5. Response to ferrous sulfate given orally was good in 64 of 67 patients in whom the follow-up period was sufficient for the evaluation of the results of treatment. The average daily rise in hemoglobin was 0.25 gm. per 100 ml. Although deficiencies in several nutritional factors were present in the examined group of undernourished children, the iron deficiency accounted for the anemia.

Changes of Serum Total Lipids.—Cases of myocardial infarction or other manifestations of atherosclerosis are rare among Jews of Yemenite origin who form about 6% of Israel's population. Dreyfuss reported two patients with myocardial infarction among Yemenite Jews but noted that one of the patients had lived in Israel for 35 years and the second for 21 years. Among the 650 patients with myocardial infarction admitted to the Beilinson Hospital in the period 1936 to 1954, none were of Yemenite origin, according to a review of M. Toor and his coworkers reported in the *Bulletin of the Research Council of Israel* (4:202, 1954). One Yemenite Jew admitted to the Beilinson Hospital, however, did suffer from generalized atherosclerosis. This patient had been living in Israel for 38 years. Accepting the general idea that a direct relation between the concentration of the serum cholesterol and the development of atherosclerosis may exist, the authors determined the values of serum cholesterol, total serum lipids, and phospholipids in two groups of Yemenite Jews: 75 who had lived in Israel for 20 years or more (old immigrants), and 192 who came to the country 3 to 5 years ago (new immigrants). In each age group for both men and women the level of total lipids, total cholesterol, and phospholipids was higher in the old immigrants.

Brunner and his co-workers examined four groups, each consisting of 50 normal men in the age group of 35 to 60 years (*Harefuah* 48:4, 1955). The four groups were: Ashkenazi Jews; Yemenite Jews living in the country more than 30 years; Yemenite Jews living in Israel 4 years and less; and Arabs. The authors also presume that the morbidity and mortality of myocardial infarction and arteriosclerotic vascular disease among Ashkenazi Jews in Israel is similar to that of the general population of the Western world; however, myocardial infarctions are rare among Jews from Moslem countries and almost never are found among Yemenite Jews. The cholesterol levels as well as the phospholipid ratios were particularly low in recent immigrants from Yemen. The Yemenites living in Israel for more than four years had statistically significant increases in cholesterol values but no change in their phospholipid levels. Thus, while the cholesterol levels were lower than those of Ashkenazi Jews, the ratios were similar. Both cholesterol and phospholipid levels were about equal in both the Arabs and the old Yemenite Jews. The factors responsible for these differences in serum levels may be related to differences in nutritional habits and the increased stress of modern civilized life. The rise in cholesterol levels among Yemenites with lengthening stay in Israel must be considered as a typical reaction of acclimatization.

New Hadassah University Hospital Psychiatry Department.—The first batch of patients have now been received by the department of psychiatry at the Hadassah University Hospital in Jerusalem. According to Prof. Milton Rosenbaum of Cincinnati University, the acting director of the department, the major goal is to produce more psychiatrists familiar with dynamic psychiatry. Professor Rosenbaum has come for a year to guide the establishment of the unit. Once a week there will be conferences with the medical services on psychosomatics and a pediatric session jointly with physicians of the children's wards. A group of psychiatric specialists, some from the Hadassah Medical Organization, have volunteered their help in teaching and guiding the growth of the unit. They complement a full-time staff of three physicians, a psychologist, an occupational therapist, a social worker, and nurses. Professor Rosenbaum stated that the department would have a psychoanalytic orientation.

ITALY

Medical and Surgical Convention.—At the Medical and Surgical Convention in Montecatini in May, Professor Campanacci of the University of Bologna reported on 120 patients in whom a gastric resection was made. The results were excellent in 60% of the patients, satisfactory in 28%, and unsatisfactory in 12%. They were definitely worse in women. Postoperative complications included the dumping syndrome, the dyscrasic-edematigenous syndromes, the hepatobiliary syndromes, and the hematological syndrome. The speaker considered the disappearance of pain in most patients and the reduction in the secretion of hydrochloric acid as favorable signs and a neuroendocrine-vegetative lability, which consisted of hypoadrenal hyposympathicotonus, dysproteinemia, and early or late postprandial syndromes, as an unfavorable sign. He said that the postoperative neurovegetative lability is not a new finding in patients who have undergone resection, but it is the accentuation of a preexisting condition that is characteristic of patients with ulcer. The postprandial syndromes are caused not only by alterations of the glucide, electrolyte, and protein balance but also by a reduction of the reservoir function of the stomach. In view of this, a new therapeutic regimen consisting of a diet that is regulated qualitatively and quantitatively and taken at proper intervals should be used; the foods allowed should not be too fluid, too warm, or too cold; sweets should be avoided; carbohydrates should be restricted; an adequate quantity of fats should be maintained; animal and vegetable proteins should be increased; a constrictive girdle should be worn; and the habit of lying down after a meal to avoid the onset of those postprandial syndromes that are mainly of a mechanical nature (dumping syndrome) should be practiced. It is therefore necessary to control the eventual depletion of amino acids, iron, digestive enzymes, vitamins, hormones, and especially of desoxycorticosterone acetate, cortisone, gastric mucosa derivatives, calcium, and vitamin B_{12}.

Professor Forni and his co-workers reviewed the results obtained in 1,000 patients. Gastroduodenal resection aims at removing the ulcerative lesion and decreasing the gastric secretion of hydrochloric acid. The removal of the lesion is achieved in all the patients, but hypochlorhydria is achieved in only 50 to 60%. The speaker's results were mediocre or poor in 15%. The best results are obtained in gastric ulcers (93.8%) and duodenal ulcers (81.5%) in men; the results are less satisfactory in women. Good results are also obtained in patients with ulcers complicated by stenosis, hemorrhage, and perforations. Success is more easily attained in middle-aged and aged patients and is less common in patients under 20. The best results are observed in those patients whose preoperative hyperchlorhydria was due to a histaminic stimulus. The absolute indication for resection is a duodenal ulcer that is accompanied by a complication or by a syndrome resistant to all medical treatment. A relative indication is the patient's age. Contraindications are a complicated ulcer in a young patient, a constitutional state of anxiety, and tuberculosis.

SWEDEN

Barbiturate Poisoning.—Profound changes have taken place in the treatment of barbiturate poisoning in recent years. Dr. B. Herner in *Nordisk medicin* for May 5 reports 118 patients with acute barbiturate poisoning who were treated during the period 1950 to 1954. Twenty were so serious that the patients were unconscious for more than 24 hours, but only four died. Much of the credit for this high recovery rate goes to the prevention of infections by antibiotics, the prevention of shock by the parenteral administration of fluids, blood transfusions, oxygen inhalation, and keeping the respiratory passages clear. Another factor seems to be the modern switchover from long-acting to rapidly acting barbiturates. Herner urges his colleagues to promote this trend, and he looks forward to the time when the soporifics most in use will be derived from the antihistamine group instead of the barbiturate group. Wisborg and Schuback in *Svenska läkartidningen* for May 6 report 239 patients with barbiturate poisoning in the period 1945 to 1954. In the first half of this period such patients constituted only 0.4% of all the admissions, whereas the corresponding figure for the second half of this period was 1.5%. The cause of death in the 13 who died was bronchopneumonia in 6, heart failure in 5, pulmonary embolism in one, and uremia in one. The authors condemn the use of long-acting barbiturates, the slow excretion of which is one cause of death in these patients. While the men were outnumbered by the women in the ratio of 1:1.69, the mortality rate for men was only 4.3%, whereas that for women was 6.1%. The distribution of these 239 cases by months was surprisingly even, but May was the worst month, and the summer was worse than the winter.

Chlorpromazine in Psychiatry.—Dr. O. Hagnell and his co-workers in *Nordisk medicin* for May 5 reported 130 psychotic patients of recent and of long standing who were given 50 to 100 mg. of chlorpromazine three times a day. A total of between 2 and 5 gm. were given by injection followed by a total of between 5 and 10 gm. by mouth. The authors concluded that this treatment should not be considered ineffective till it has been tried for at least six weks. They have observed several severe complications, which in two patients consisted of great anxiety, promptly ceasing when the drug was withheld. In 3 patients there was evidence of serious damage to the liver, and in 68 the sedimentation rate increased more than 10 mm. per hour during the treatment. In spite of these complications this treatment evidently deserves further trial provided careful laboratory control is assured. In the same issue Dr. S. Cronqvist and his co-workers reported 54 patients with psychoneurosis who were treated with the same drug. This treatment began with injections of 25 mg. three times daily, the dosage being increased during the following few days according to the reaction of each patient. The results were characterized as very good in 21 patients who suffered mainly from tension, restlessness, and anxiety. A patient who had suffered for nine months from a permanent stat of terror after a mental trauma was cured after only a few day of this treatment, without any signs of relapse after it was discontinued, but as a rule the improvement could be maintaine only by continuous treatment. Because of the fairly high incidence of such complications as jaundice, urticaria, and angioneurotic edema, the authors insist that the indications for chlorpromazine treatment should be carefully considered and th patients informed of the risks before it is attempted.

SWITZERLAND

Annual Meeting of the Swiss Society of Internal Medicine.— the meeting of the Swiss Society of Internal Medicine in Genev in May Professor Gsell of Basel stressed the prophylactic a ministration of antibiotics for acute articular rheumatism. Whe deciding on the administration of an antibiotic the physici must ask himself: 1. Is the antibiotic absolutely necessary the treatment of this patient? 2. Which one is indicated? How long and in what doses should it be administered? 4. Do the antibiotic threaten to influence the body's defense reactio such as in scarlet fever, leptospirosis, or salmonellosis? 5. the development of resistant organisms to be expected? 6. C the antibiotic produce toxic side-effects? Prof. G. Bickel Geneva stated that side-effects produced by antibiotics may caused by the inherent toxicity of the products used, by sen tivity reactions on the part of the patient, or by a biologi effect secondary to the action of the antibiotic on the mic organisms.

Professor Sheehan of Liverpool described the characterist of the pituitary insufficiency (not anorexia nervosa) that deper on destruction of the anterior lobe by ischemic necrosis duri childbirth. He is opposed to the classic description of hyp pituitary cachexia, which he claims is an imaginary disease. a woman has significant cachexia, it is highly probable th her pituitary gland is entirely normal. True pituitary insu ciency is characterized by a normal nutritive state; the brea have a normal contour and there is no loss of hair from t head, although pubic hair is affected. These women are p and pigmentation of the areola papillaris is lacking. The syn toms of hypopituitarism resemble those of myxedema in so respects: decreased basal metabolic rate, sensitivity to cold, most total absence of sweating, marked mental torpor, puffin of the face, and anemia. The administration of thyroid produ an effect only on the basal metabolism, but the addition cortisone makes the other symptoms disappear. The resu obtained with cortisone therapy seem to indicate that ma symptoms usually attributed to thyroid insufficiency are rea due to adrenal insufficiency. The pallor of these patients explained by atrophy of the antehypophysis, which is unal to secrete intermedin.

Professor Luft of Stockholm reported on the endocrine ficiencies following hypophysectomy, which he performs the treatment of cancer of the breast, prostate, and certain ty of diabetes and hypertension. Two or three weeks after operati thyroid function is rapidly decreased and there is a fall urinary elimination of the 17-ketosteroids and the cortico Some atrophy of the genitals is noted, but there is no cache These deficiencies can be compensated for by the combin administration of cortisone and thyroid extract.

Professor Loeffler of Zurich stated that anorexia nerv manifests itself by a loss of weight that occurs mostly in wom and is due to insufficient alimentation because of an obstin refusal to eat. In young girls it is the manifestation of an u conscious desire to gain attention. Some of these patients e secretly and refuse all food in public. It is amazing that t patients are not shocked by their frightening appearance. On t contrary, they find themselves interesting and attractive. Wh anorexia follows a pregnancy complicated by hyperemesis, is difficult to make a differential diagnosis from Sheehan's sy drome. Hormone therapy has no effect, except insofar as exercises an embryonic psychotherapeutic action. The disea is properly treated by psychotherapy.

GOVERNMENT SERVICES

R FORCE

rgeon General Honored.—During the convocation ceremony the American College of Chest Physicians, held in Atlantic y on June 4, the surgeon general of the U. S. Air Force, jor Gen. Dan C. Ogle, was presented with an honorary lowship in the college, and on June 12 at Eureka, Ill., during centennial commencement of Eureka College, he was given entennial citation for outstanding achievement. He graduated m Eureka College prior to attending the medical school of University of Illinois.

rsonal.—Brig. Gen. Otis O. Benson Jr., a flight surgeon with U. S. Air Force Medical Service, on June 6 received an norary degree of doctor of science from the faculty of Mon- a State University. This distinction was accorded him in ognition of his being one of this country's leaders in the vancement of aeronautics through medical research.

AVY

mposium at New Hospital on Guam.—The naval hospital on am, June 21-23, successfully completed the first medico- litary symposium conducted by the Navy outside the conti- ntal limits of the United States. Capt. Herman A. Gross, mmanding officer of the naval hospital, was chairman and st for the meeting of military and civilian doctors from the arianas, Okinawa, the Trust Territories, Japan, and the Philip- es. Rear Adm. F. C. Greaves, M.C., district medical officer, presented the surgeon general of the Navy. The Hon. Ford Q. vidge, governor of Guam, welcomed the guests to the island. e consultants for the symposium were Drs. Winchell M. Craig, ofessor of neurosurgery at the Mayo Clinic, Rochester, Minn.; uce Anderson, director of anesthesia, Samuel Merritt Hospital, kland, Calif.; T. Eric Reynolds, former surgical consultant Admiral Halsey; Gerald Gray, plastic surgeon, Oakland, lif.; Edwin Bannick, Seattle; William Rogers, clinical professor surgery, Stanford University School of Medicine, Stanford- n Francisco; Walter Work, otolaryngologist consultant at tterman Army Hospital, San Francisco; Harry Walker, former ief of orthopedic service, U. S. Naval Hospital, Oakland, lif.; and Capt. W. Van Zile, D.C., chief of dental service, d Commander Leonard Barber, M.C., radiologist, U. S. Naval ospital, Oakland, Calif.

ew **Director of Pathology Institute.**—The Department of efense announces the appointment of Capt. William M. lliphant, M. C., U. S. N., as the director of the Armed Forces stitute of Pathology, Washington, D. C. The Armed Forces stitute of Pathology serves as the central laboratory of pathol- y for all the armed services and for the Veterans Administra- on and on a voluntary basis for the U. S. Public Health Service, e Atomic Energy Commission, and other federal medical encies. The 54-year-old veteran Navy pathologist succeeds rig. Gen. Elbert DeCoursey, M. C., U. S. Army, whose tour duty ends on Aug. 1 and who will become commandant of e Medical Field Service School at Brooke Army Medical enter, San Antonio, Texas. Captain Silliphant, deputy director nce 1952, was nominated by the board of governors of the rmed Forces Institute of Pathology, composed of the surgeons eneral of the Army, Navy, and Air Force. This assignment is ormally for four years and rotates in order among the Army, lavy, and Air Force.

Captain Silliphant was commissioned in the Medical Corps of e Navy in 1930. In 1933 he began postgraduate study in athology at the Naval Medical School and since then he has erved as pathologist and laboratory officer at various naval ospitals. Assigned to the Philippine Islands one month before the Japanese began their conquest of those islands, he was captured and interned for 37 months. Returning home after liberation of the Philippines in 1945, he served as chief of medicine and pathologist at the Naval Hospital, Long Beach, Calif., and in 1947 was transferred to the Naval Medical School, Bethesda, Md., where for five years he was director of laboratories, executive officer and consultant to professional division, Bureau of Medicine and Surgery. In 1953, he was sent to the Far East for survey studies on Korean casualties, with particular reference to the influence of body armor on war wounds. Captain Silliphant is a diplomate of the American Board of Pathology. He has contributed articles on bronchogenic carcinoma, eosinophilic granuloma, wound ballistics, and comparative studies of the Kahn and cardiolipin tests for syphilis. For distinguished service while a prisoner of war, the Secretary of the Navy issued him the Navy Letter of Commendation. He was also awarded the Army Distinguished Unit badge, Philippine Defense, 1941-1942; and, from the Philippine government, the ribbons of Philippine Defense, Philippine Liberation, and Philippine Independence.

New Editor Appointed.—Capt. Bennett F. Avery, M. C., has been designated director of the Armed Forces Medical Publication Agency. As director of the agency, Captain Avery will be the editor of the *United States Armed Forces Medical Journal* and the *Medical Technicians Bulletin*. He succeeds Col. Robert J. Benford, U. S. A. F., who has been assigned to duty in the office of Dr. Frank B. Berry, the assistant secretary of defense (health and medical).

Personal.—Rear. Adm. Bartholomew W. Hogan, M. C., surgeon general of the Navy, received the honorary degree of doctor of science from Boston College and Tufts University recently.

PUBLIC HEALTH SERVICE

Dr. Sebrell to Retire from Service.—Assistant Surgeon General William H. Sebrell Jr., who has been director of the National Institutes of Health, will retire on Aug. 1, following 30 years of service. He will be succeeded as director of the National Institutes of Health by Dr. James A. Shannon, presently associate director of the Institutes. Dr. Sebrell has accepted appointment as research consultant to the American Cancer Society and will direct the society's institutional research grants program. Commenting on Dr. Sebrell's retirement, Surgeon General Scheele said: "His directorship has been invaluable in bridging a complex period of transition, not only in our own expanding research program but in medical research the world over. Dr. Sebrell, drawing upon a distinguished background of active research and administration, has been one of the nation's leaders in the new research attack on disease, particularly the chronic diseases, such as heart disease, cancer, and mental illness." Dr. Sebrell has earned a world-wide reputation as a medical scientist, particularly through his studies on the B vitamins. He has also received scientific acclaim for important findings in the dietary cause and treatment of liver disease, the effect of pantothenic acid deficiency on the adrenal glands, the nutritional effects of sulfonamides, and the cause and treatment of blood abnormalities.

Dr. Shannon, the new director, has been associate director since November, 1952. He is also chairman of the service's technical committee on poliomyelitis vaccine. Prior to 1952, he was associate director in charge of research at the National Heart Institute. From 1946 to 1949, he was director of the Squibb Institute for Medical Research. He then came to the Public Health Service as a commissioned officer.

Dr. Shannon is a member of the American Physiological Society, the American Society for Clinical Investigation, the Society for Experimental Biology and Medicine, the Harvey Society, and the National Malaria Society. He is a member of the Alpha Omega Alpha and Sigma Xi professional fraternities.

CORRESPONDENCE

LOCAL INJECTION OF HYDROCORTISONE TERTIARY-BUTYLACETATE IN SKIN LESIONS

To the Editor:—In spite of the efficacy of topical applications of ointments and lotions of corticosteroids in certain common skin conditions, such as infantile eczema, atopic dermatitis, pruritus ani, and mild contact dermatitis, direct intralesional injections are still necessary and practical in treating lesions that do not respond readily to topical applications. In this list are small patches of psoriasis, especially on exposed areas; small patches of discoid lupus erythematosus, still persistent after systemic therapy with chloroquine or chlorochloroquine; keloids; localized myxedema; localized scleroderma; granuloma annulare; and small areas of leukemic lesions or other specific cutaneous lesions of the lymphomas. A second group of lesions for which injections may be used includes those that may respond in part to topical applications, especially small areas of the deep lesions of localized neurodermatitis.

We have used suspensions of hydrocortisone acetate and alcohol with an ordinary syringe and needle, also in the cartridge type of syringe (Goldman, L., and others: *A. M. A. Arch. Dermat.* **71**:157 [Feb.] 1955), and with Hypospray jet injection apparatus. Noting the good and persistent response of hydrocortisone tertiary-butylacetate in intra-articular injections by J. L. Hollander (*Ann. New York Acad. Sci.* **61**:512 [May 27] 1955), this suspension has been used by us routinely, in both clinical and investigative studies, for the last past five months. Fifty-eight injections have been given, varying volume from 0.1 to 0.3 cc. (25 mg. per cubic centimeter). The suspension is easier to inject than the suspension of hydrocortisone acetate. A 27 gauge needle may be used for facial lesions and a 25 gauge needle elsewhere. The material appears to be as effective locally as the hydrocortisone. The same essential histopathological changes have been found in the skin of man as have been found with hydrocortisone and its other analogs. Histochemical studies also show the same changes in the tissue (Goldman, L.: *Ann. New York Acad. Sci.* **61**:520 [May 27] 1955). The crystals may persist in site for at least five to six months. This fact must be considered when local injection therapy is used.

ADENOIDECTOMY

To the Editor:—May I reply to Dr. R. T. Barton's protest (The Journal, June 11, page 505) of my statement that "deafness, recurring otitis media, and mastoiditis are rarely improved by adenoidectomy," a quotation taken from an abstract in The Journal Dec. 11, 1954, page 1461. In disagreeing with the above statement, Dr. Barton is undoubtedly voicing an opinion generally held; however, my article and The Journal's abstract of it would have served little purpose if they had not mentioned the fallacies of the prevailing belief. Many outstanding men believe that progressive deafness, recurring otitis media, and mastoiditis usually are caused by chronic sinusitis and that adenoidectomy not only fails to improve these conditions but may predispose to them. In the original article (Harmful Sequelae of Adenoidectomy in Children with Chronic Sinusitis, *Arch. Pediat.* **71**:233, 1954) there are 64 references and many quotations regarding the protective value of adenoids against the purulent secretions of sinusitis in the production of the above conditions by sinusitis. Those quoted include H. B. Lemere, T. B. Layton, A. D. Kaiser, G. B. McAuliffe, E. C. Marantz, J. A. Glover, J. Wilson, M. M. Cullom, H. M. Taylor, G. E. Martin, J. Crooks, and A. G. Signy.

The adenoid protects not only the upper but also the lower respiratory tract. Kaiser's controlled study, now a classic, has shown that removal of tonsils and adenoids increases the likelihood of lower respiratory tract symptoms. As my article state these complications are seen only in children with sinusitis who protective barrier, the adenoids, has been removed. It seen neither fair nor open-minded for one to protest a stateme appearing in an abstract when he has not read the original artic to determine how the conclusion was derived.

IODIDE AND ASTHMA

To the Editor:—The Correspondence article by Dr. Leon Ung entitled "Orders for Patients with Asthma," which appeared the June 11, 1955, issue of The Journal, page 505, was exceller I would, however, like to make a correction and an additio Under direction 7, for severe cases, Dr. Unger orders pota sium iodide drams 5 and parenthetically states it equals 8.86 g This is incorrect, as 5 drams equal 300 grains or approximate 20 gm., a difference in his dosages of almost 6 grains per te spoonful between his dram and metric orders. My preferen is to start with the smaller dose, to determine the tolerance the patient for iodides, as they can at times be very irritatin The list might include sodium iodide, intravenously admin tered, 15.5 grains (0.97 gm.) in 10 cc. distilled water, which useful in bronchial asthma due to thick mucus plugs. I ha seen status asthmaticus cases dramatically relieved with t expulsion of large amounts of thick mucus by its use. All phy cians should be familiar with Dr. Unger's fine article, especial the point on not giving morphine to one in an asthmatic attac

New York 57.

THE CADUCEUS

To the Editor:—I realize that The Journal staff is not sponsible for the inaccuracy that appears on page 506 of t issue of June 11, 1955. A notice on that page refers to a n insigne to be worn by medical and dental officers of the Force. A serpent is not a caduceus. The caduceus (there is or one) is the winged staff of Mercury, who was the Greek patr god of speed, of messengers, of merchants, of thieves, and othe The snakes entwined about Mercury's staff are represented the position of coitus, signifying cooperation and fertility. I ha never known how the erroneous association of the caduceus wi medicine arose, but it persists even now in many areas. As y well know, the American Medical Association long ago cc rected this error and adopted as its emblem the staff Aesculapius, the same as that on the new Air Force medic insigne.

INSURANCE FORMS

To the Editor:—In our increasingly complex civilization, ste to safeguard the security of our population have very rightl increased progressively. This is reflected by the number of form for insurance companies that the physician is constantly calle on to fill out. Although this is an important and necessary pa of his work, it would be made much easier if the insurance com panies, instead of submitting single forms to fill out, would sub mit duplicates so that file copies might be kept. I am sure tha no insurance company would fill out any form without havin a duplicate form to keep in its own file. I cannot understan why they expect the physician to conduct his practice in suc a slipshod manner. I have adopted the policy in my office o not filling out insurance forms unless they are submitted in duplicate. How do other readers feel about this?

MISCELLANY

IE PATIENT'S STAKE IN ACCREDITATION

bert S. Myers, M.D., Chicago

Reprinted with permission of the author from the Bulletin of American College of Surgeons (*July-August*).—Ed.

Hospital accreditation is the hallmark of patient safety. It is official recognition of a hospital's voluntary conformation desirable standards of adequate patient care. It is a reliable, sily accessible guide for public use in the selection of a hos- al. Although accreditation is to the hospital world what rling is to silver, it is a strange and unknown term to the neral public.

There are three main reasons why the public knows so little out the meaning of accreditation. In the first place, patients ect doctors rather than hospitals, and their physician's staff pointments usually determine the patient's choice of a hos- al. This is a well-deserved tribute to the medical profession, t it does not always lead to the selection of the accredited spital and an appreciation of its value by the patient.

Secondly, the program of hospital accreditation is a mere ant which attained its growth during a hectic period of de- ssion, wars, and fabulous medical scientific discoveries. That program did not perish is a tribute to the American College Surgeons, which conceived it in 1918 and carried it single- nded through the next 35 years. In 1952 the program of reditation was transferred to the Joint Commission on creditation, which is composed of representatives from the nerican College of Physicians, the American College of Sur- ons, the American Hospital Association, the American Medi- Association, and the Canadian Medical Association.

The Joint Commission adopted the standards found to be sirable by the College during its years of administering the ogram and is now in the process of clarifying, revising and engthening certain portions of these. Twenty physicians, ll-trained in all aspects of patient care, are supplied to the int Commission by the parent organizations for inspection its to hospitals in all parts of the United States and Canada. the hospitals in these two countries which have applied for reditation approximately 3,200 have met the rigid require- nts. [*There are now 21 physician-surveyors; and as of De- nber 31, 1954, a total of 3,513 hospitals were accredited by Joint Commission.*]

The third and main reason for the lack of public knowledge ncerning accreditation is the inherent conservatism of the edical profession and hospitals and their aversion to publiciz- g their accomplishments. Such reticence is often commend- le, but the best interest of the patient has not been served by ch unnatural reserve. Every opportunity should have been ized to inform the public of the demonstrated worth of accreditation in guarding the welfare and safety of the patient.

Accreditation is not a device to enrich the coffers of hospitals the pockets of doctors. Accreditation has cost hospitals an told amount of money; it has multiplied the work of the medi- l profession; it exacted approximately $2,000,000 from the llows of the American College of Surgeons during the first years; and it now requires half a million dollars each year om the funds of the agencies composing the Joint Commis- on. All this has been done gladly and for one purpose only e benefit of the patient. Surely these facts are worthy of the lling.

What more should the patient be told about accreditation? is proper to inform him of the unceasing efforts taken to rovide him with a suitable, sanitary physical plant which is dequately protected against fire and explosion hazards. He should be told of the need for proper diagnostic facilities, including x-ray and laboratory departments. Mention should be made of the many instruments required to maintain a surgical department and the equipment necessary to sterilize these instruments and other materials. He should know about the hospital pharmacy, which is often as extensive and expensive as the corner drug store. Few patients will realize that the hospital dietary department often serves more meals daily than many hotels in the community. He will be surprised to learn that special diets must be prepared for the patient with diabetes, heart disease, or intestinal trouble. He does not realize the extensive planning and multiple safeguards necessary to protect the newborn infant. Each such activity is but one facet of the hospital.

There are also the many highly trained people required for the adequate care of the patient—record librarians, nurses, dietitians, x-ray and laboratory technicians, pharmacists, physiotherapists, occupational therapists, social service workers, maintenance men, housekeepers, purchasing agents, maids, orderlies. Hidden below the surface, like the main body of an iceberg, many of these vital personnel are not visible to the patient during his hospital stay, but they are an absolute necessity, and they cost money.

Many uninformed patients who complain about the high cost of hospital care compare hospitals with hotels, which make money with lower daily charges. The public should be told about the costly and unique equipment required by hospitals and the many specialized personnel needed to serve the patient 24 hours a day. The patient doubtless has never thought of the expense involved in guarding his life and health, and it has never occurred to him that such profitable sidelines as liquor sales are not revenue producers for hospitals.

What is required of the medical staff of an accredited hospital? The program of accreditation has conclusively demonstrated that the medical staff of the hospital holds the key to accreditation through a series of self-imposed controls or standards designed to protect the patient. This voluntary effort of the profession to maintain adequate standards of patient care is usually not apparent to the public.

Detailed histories and physical examinations must be made for the protection of the patient. Complete medical records must be dictated promptly, operative notes written and consultations recorded. Radiologists are required for searching diagnostic studies, and every bit of tissue must be examined by the pathologist. Skilled anesthesiologists are required to administer the anesthetic and are expected to follow the patient until he recovers from anesthesia. Such activities of doctors are not haphazard occurrences. They are part of the integrated activities of an organized medical staff found in an accredited hospital.

Little does the patient realize the time and effort demanded of the physician to serve as a member of the five essential medical staff committees required for accreditation of a hospital. The executive committee sets staff policy and provides discipline; the credentials committee assesses the qualifications of physicians and assigns them to privileges and to departments; the joint conference committee consults with the governing board on problems of interest to the board and medical staff; the medical records committee examines countless records, evaluates their contents and assesses the care of the individual patient; the tissue committee reviews every operation and decides the justification for surgery.

In order to inform the medical staff about the quality of patient care so that it may be maintained at the highest level, physicians are required to meet at regular intervals. There are monthly medical staff meetings, weekly or monthly departmental meetings and clinical pathological conferences, to say nothing of the nonrequired but equally educational county, state and national medical meetings and conventions of various specialist societies.

Does the patient know that accreditation requires a competent administration, composed of a trained and experienced administrator and a governing board selected for its knowledge, interest and experience in hospital affairs? To this segment of the hospital falls the grave obligation of assuming moral and legal responsibility for the welfare and safety of the patient in addition to the financing and direction of the hospital.

Assistant Director, American College of Surgeons.

[Presented at the Catholic Hospital Association's thirty-ninth annual onvention, Atlantic City, New Jersey, May 19, 1954; and, with amend- nents, reprinted with permission from *Hospital Progress*, August, 1954.]

And, finally, the patient should be told that accreditation places the responsibility for medical ethics squarely on the medical staff and the administration of the hospital. This is vitally important to the patient for adequate control helps protect his health, his life and his pocketbook. Unethical or unprofessional conduct consists of more than unjustified surgery or the unnecessary or unsanctioned removal of normal organs. Fee-splitting and ghost surgery exist in some hospitals, regardless of size, location or religious affiliation. All these evils must be regarded as morally wrong, and it is time for the medical profession and hospitals to close ranks to eliminate those who violate the principles of medical ethics and bring discredit on honest physicians and hospitals.

It is heartening to witness the recent vigorous demands from all segments of the medical profession and from administrators of numerous hospitals for eradication of unethical practices. As long as doctors are human, there will be transgressors among the medical profession, but no other business, trade, occupation or profession contains so many able, dedicated men and women devoted to the betterment of mankind as the medical and hospital professions.

How should the public be informed about the benefits of accreditation? There are several steps worthy of consideration. First, members of the medical profession should demand that all hospitals in which they work gain accreditation, and they should insist that their patients enter only accredited hospitals for treatment. Moreover, the profession, working through local medical societies, should inform the public of the benefits of accreditation by newspaper articles and by talks to lay groups.

Hospitals should supplement this public information program by distributing to patients factual and informative pamphlets concerning the patient's stake in accreditation. This is an era of brand names and accepted products. An intelligent public wants the best, but it cannot be expected to appreciate anything as intangible as accreditation unless it is properly informed. The accredited hospital is a blue ribbon product, and it needs to be publicized.

There have been suggestions from the medical profession and hospitals that accreditation should be made compulsory by local government health agencies which would demand accreditation by the Joint Commission as a requirement for government licensure of a hospital. There is some doubt that such action would be entirely wise. Accreditation has been voluntary from its inception 36 years ago and every effort has been made to avoid even the suggestion of compulsion. The program has been entirely free from discrimination against race, creed and color, and, most important of all, political and other undesirable influences have never affected the decisions of the accrediting agencies.

It is not certain that such integrity could be maintained in any liaison with government. The co-operation among the parent organizations comprising the Joint Commission has been most heartening, and the program of accreditation is being strengthened and expanded. Public demand for accreditation will accomplish the objectives of government action without sacrificing the advantages of integrity and freedom from undesirable influence now enjoyed by the Joint Commission.

Privileges bring responsibilities, and the patient bears certain moral obligations in return for the benefits he receives from accreditation. It is to be expected that he will patronize those hospitals whose physicians and administration have sacrificed time, money and effort to obtain accreditation for his benefit. Moreover, the patient must recognize that the standards of accreditation proscribe surgery and medical treatment in the absence of specific medical indications. The patient's request alone is not a valid indication for specific surgical procedures or medical treatment, and the patient must not demand special consideration in violation of accepted principles of accreditation.

If the medical profession and hospitals believe that their prime concern is the welfare and safety of the public, they are irrevocably committed to the program of accreditation, and it should be their combined objective to educate the public about the benefits of accreditation. Anything less is a betrayal of our medical ideals.

THE LEISURE CORNER

LOOKING AT MODERN ART

Perhaps among no other group of professional persons an interest in painting and sculpture been more extens cultivated than among American physicians. Thousands of p cians have translated their interest into action by joining ranks of Sunday painters, starting modest collections of pain and sculpture, or avidly attending art exhibitions. While exact relationship between art and medicine has never defined to the complete satisfaction of the two types of p tioners, both disciplines have much in common. Capable p cians and artists have a quick eye, possess manual dext entertain a sympathetic interest in their environment, and e a comprehensive understanding of their fellow human bein

In order to understand contemporary art or, for that m the art of any historical period, it is necessary to view a terms of the society, culture, and era that produced it. U science, there are no absolute standards by which art ca measured, there are no authorities whose judgment can be to be omniscient, and there is no single, correct way to lo a painting or a piece of sculpture. Although the role of the has been variously interpreted at different times, Sieg Giedion offers this succinct observation: "The artist," he as "in fact, functions a great deal like an inventor or a scie discoverer: all three seek new relations between man an world. In the artist's case these relations are emotional in of practical or cognitive. The creative artist does not wa copy his surroundings, on the one hand, or to make us see through his eyes, on the other. He is a specialist who sho in his work as if in a mirror something we have not realize ourselves: the state of our souls. He finds the outer syn for the feelings which really possess us but which for u only chaotic and—therefore—disquieting, obsessive stin This is why we still need artists, however difficult it may b them to hold their place in the modern world."

While many persons are more accustomed to reading a art in magazines and newspapers, the opportunity to look picture, "in the flesh" as it were, would not only develop sensitive perception but also increase enjoyment. This me has provided many contemporary artists with a new vocab to explain, portray, and interpret the vast numbers of and auditory stimuli that bombard 20th century life. Mo art is more concerned with expression than with represent with creation rather than with imitation. If anything, mo art is characterized by various styles and various technique experiment, by daring, and by lack of conventionality.

Cubism provides one of the most significant developmen modern art. In order to appreciate a cubist painting, a spec should stop being a passive onlooker; instead, he should ma serious attempt to identify himself with the artist and fo the development of the painting step by step. For examp cubist painter will start with a known object as his poin departure and attempt to show all sides of it at one time, th front, back, sides, inside, top, and bottom. In short, what he to do is depict the entire object visually as a single experie

As can be surmised, cubism permits an artist considerable dom. Despite the fact that the artist uses a known object as basis for his work, he will take many liberties while pain combining aspects that ordinarily escape the spectator's eye. intent of a cubist painting is neither psychological nor liter in essence, it provides a new method and a new visual langu to extend the possibilities of experience. Since cubist painters more interested in transforming an object than in transform a subject, they manipulate their material at will.

Futurism began to interest a number of artists several y after the advent of cubism. This aspect of modern art is c cerned with motion. In both cubism and futurism the dissec of form is combined with a constant reassembling process.

This article is based in part on material drawn from a book wri by Katharine Kuh: "Looking At Modern Art," Art Institute of Chic 1955.

jects are disintegrated only to be put together in new combinations, so that complete form and motion are recorded in single visual experiences. A notable difference between cubism and futurism lies in the fact that cubist painters combine all sides of an object simultaneously, while futurist painters attempt to express complete motion at one time. The goal of a futurist painter is not so much to suggest motion—this has been done in the past—but actually to depict and capture motion on canvas or paper. Futurist painters have tried to accomplish this by a series of overlapping forms that illustrate the path of an object as it moves through space. They did not merely want to show a man running—what they wanted to do was to show the running of a man, in fact, the continuous running of a man at a given time. Marcel Duchamp's famous painting "Nude Descending a Staircase," was *in one sense a motion-picture technique* that anticipated the results of the dissection of motion by the stroboscopic camera.

As employed today by the *cognoscenti* of the modern art world, the term expressionism has more than one meaning, although it chiefly implies emotional expression. In general, an expressionist painter will sacrifice a naturalistic appearance for a *completely personal interpretation, producing an emotional* feeling of a scene rather than its visual counterpart. This is accomplished by exaggerating color, form, line, and space.

Psychoanalysis has provided some artists with source material for their work. A case in point is surrealism, which is concerned mainly with irrational dream material. In an effort to escape the difficulties and ennui inherent in much daily life, the early surrealist *painters claimed that dreams supplied the only reality* and it was through dreams that emotions could be released; hence, the name of this particular art movement—sur (super) realism. In surrealism, barriers of time as well as moral judgments are frequently eliminated and the painter arranges a combination of unconscious experiences on a single canvas where the past, the present, and intervening psychological states are superimposed.

The art movement known as Dadaism had a basic philosophy that differed from that of surrealism, which it antedated. Dadaism evolved during the First World War as a protest against war, and it attempted to escape disillusionment by complete negation. The eminent critic, Lewis Mumford, once called Dadaism "an irreverent commentary on the inflated platitudes of politicians," and Clifton Fadiman facetiously referred to the late Gertrude Stein as "the Mamma of Dadaism." On the other hand, modern technology and science have given artists a wealth of new materials and new approaches for using old materials. As a result, contemporary artists have had greater opportunities for experimentation. The mobile, a new kind of sculpture, provides a good example. The development of the mobile can be traced to contemporary interest in motion and the diversified use of materials. Heretofore, most sculpture has been static, occasionally suggesting movement but not participating in movement itself. The mobile, which is based on the idea that its various parts are flexible, is designed for motion. As it moves, the mobile presents numerous relationships to the spectator. Generally, an observer must move around three-dimensional sculpture in order to see it properly. Since mobiles presuppose that both the sculpture and the spectator *move, many changing aspects can be* seen at one time.

In recent years, a new school of painting that can loosely be described as abstract expressionism has been gaining adherents in the United States and Europe. As in the case of surrealism, abstract expressionism is geared more to the needs of the artist than to the immediate understanding of the general public. Abstract paintings are frequently filled with allover patterns devoid of a beginning or an end. Form is relatively unimportant —mood is what counts. There is apparently no one central idea, no preliminary sketch in a painting classified as abstract expressionism. An abstract composition will provide an artist with an immediate experience in which he depicts what he feels at the moment, and this culminates in completely abstract designs.

For many people contemporary art and sculpture is either a joy or a puzzle. Nonetheless, its influence has been felt in every nook and cranny of American life. If there is any doubt, one need only look at modern furniture, architecture, transportation, and household appliances, to name an important few. Whatever the attitude of artists and spectators may be to certain aspects of modern art, it would be well to keep in mind the point of view that has been expressed by Katharine Kuh. "In our own way of life," she declares, "each man is allowed to express himself independently; each artist can work as he wishes. So also the spectator, sharing this same freedom, is entitled to form his own judgments. No government imposes its will, no one school of art can dictate policy in a field so open to competition. . . . One need only observe the sterility of art under dictatorships like Nazi Germany or Soviet Russia to realize how official directives and censorship obstruct creative expression and enforce uniformity."

MEDICAL FILM REVIEWS

The Magic Touch: 16 mm., color, sound, showing time 9 minutes. Educational Collaborator: Edward G. Johns, Ed.D., Department of Health Education, University of California at Los Angeles. Produced by and procurable on purchase ($90) from Avis Films, Inc., 932 N. LaBrea, Hollywood 38, Calif.

The purpose of this film is to counteract apprehensions in regard to immunization by showing (1) how immunization protects the body against disease and (2) how insignificant the mild discomfort of being immunized is in comparison to the benefits derived. Sally, Jill, and Jerry are members of an elementary school class that is visited by the school nurse preparatory to immunization. The nurse's talk covers the two points described above. Because they understand and appreciate the nurse's message, the children are not apprehensive when they undergo actual immunization, and as a result of their proper attitude they find that the "magic touch" is indeed a slight discomfort. At home, the children play "doctor and nurse," with Sally's doll as patient, to recapitulate and emphasize the lessons they have learned from the school nurse and from their own experiences in being immunized. This is a well-acted film on the need for immunization. Technically, the method of flaming the needle and of using the same needle for successive injections is questionable. The possibility of the spread of infectious hepatitis suggests the use of individual autoclaved needles. In addition, the possibility of the transformation or precipitation of the proteins in the toxoid by heating the small amount left in the needle could produce untoward sensitizations. The use of the public health nurse for classroom teaching varies from community to community. This film is suitable for showing in the classroom and to parent-teacher groups.

A Matter of Time: (Cleared for Television): 16 mm., color, sound, showing time 14 minutes. Produced in 1954 by *Unifilms for the Institute* of Life Insurance, under the technical guidance of Dr. Francis R. Dieuaide, Director of the Life Insurance Medical Research Fund. Procurable on loan from Association Films, Ridgefield, N. J., and regional libraries of Association Films.

This film shows the laboratories, hospitals, and medical schools where scientists and researchers are seeking a cure for heart disease. Such research developments as the "jiggle-bed," oscillograph, and the mechanical heart are featured, with an explanation of the causes and effects of various forms of heart disease. Animation and scale models are used to illustrate the four types of heart disease: arteriosclerosis, hypertension, rheumatic fever, and congenital malformations. The film also suggests aids to the average person in avoiding heart disease and attaining a longer, healthier life. There are innumerable parts that are *not understandable to laymen, particularly the photo*micrographs of arterial sections, many unexplained sequences of laboratory devices, and charts. Apparently, the film is designed to impress people with the need to protect their hearts, but this objective has not been reached. The very positive statement, given in at least two instances, that heart diseases will be conquered in time is not particularly reassuring when one knows the relative impossibility of that in the modern classification of disease and the tabulation of causes of death. With a good discussion leader, this film would be suitable for service and hospital groups, heart association workers, and for health education at the college level.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Adams-Stokes Syndrome: The Treatment of Ventricular Asystole, Ventricular Tachycardia and Ventricular Fibrillation Associated with Complete Heart Block. S. R. Robbin, S. Goldfein, M. J. Schwartz and S. Dack. Am. J. Med. **18**:577-590 (April) 1955 [New York].

Four cases of heart block with Stokes-Adams syndrome are described in two men and two women between the ages of 48 and 77 years to illustrate the two different mechanisms that may precipitate the attacks, namely, ventricular asystole and ventricular tachycardia or fibrillation. The approach to management should be individualized, with treatment adjusted according to the underlying mechanism. Epinephrine is the drug of choice for the treatment of ventricular asystole and should be given in a sufficient amount with the aid of electrocardiographic control. It is contraindicated when ventricular tachycardia or fibrillation is the mechanism for the attacks. Procaine amide (Pronestyl) and quinidine have been found to be ineffective and even harmful in the treatment of ventricular tachycardia or fibrillation in the presence of heart block, because of their depressant effect on the junctional tissues. Isopropyl arterenol (Isuprel) was given to two of the authors' patients. In one of them the causal mechanism was ventricular asystole and in the other, ventricular fibrillation. Isuprel stimulates the higher ventricular centers and, therefore, does not predispose to ventricular fibrillation. It appears to be the drug of choice when the basic mechanism for the Stokes-Adams syndrome is ventricular tachycardia or fibrillation and when ventricular asystole alternates with tachycardia or fibrillation in the same patient. Isuprel is given in doses of 10 to 15 mg. sublingually, four or five times daily for the prevention of attacks. For treatment during attacks the frequency of the administration and the dose must be increased, but this varies in different patients and even in the same patient depending on the patient's tolerance and requirement. One of the authors' patients required 15 mg. of the drug every hour for the first 24 hours to prevent recurrence of the attacks, and in the other patient the optimal dose was 7.5 mg. four times daily. Three of the authors' patients had atrial flutter associated with the atrioventricular block, a rare combination.

The Relation of Subcutaneous Focal Sensitivity to Referred Pain of Cardiac Origin. M. A. Kennard and F. P. Haugen. Anesthesiology **16**:297-311 (May) 1955 [Philadelphia].

The referred pain that usually occurs in the left shoulder and upper arm, but may also occur about the right shoulder and the neck, is recognized as a frequent accompaniment of the precordial distress that results from myocardial insufficiency. In some patients with chronic coronary insufficiency the referred pain becomes the outstanding symptom and the arm and shoulder become rigid and atrophic in consequence of the pain. Marked relief and return of peripheral function may follow procaine injection of trigger areas about the arm and shoulder. During the treatment of patients with cardiac disorders, the authors observed that the abnormally sensitive trigger areas lay in we defined locations and that the pain from these trigger sp always radiated in the same directions. In order to obtain mo information on the trigger sites they searched for them in patients with cardiac disorders, 35 patients with thoracic d orders not related to the heart, and 46 patients with nonthora disorders. Firm but gentle pressure of the hand and fingers w applied over the entire chest, back, and shoulders. If a pers without signs of cardiac or other disorder presses firmly on c tain areas of his chest or back he may find some spots that more sensitive than others. In these same regions, cardiac tients may be much more sensitive and the pain may be spre over much larger areas so that light pressure alone may ca them to flinch. On firm pressure the pain is discrete, stabbi and "hot." The pain remains for several minutes after the pr sure is removed in the controls. In sensitive cardiac patients is many times magnified. Both the controls and cardiac patie were completely unaware of these sensitive spots until they we examined. Furthermore, the sensitivity to pressure was not lated to their spontaneous chest pain except in a few cases. the two spots that were most frequently sensitive, one lies the chest in the midclavicular line about 1 in. below the clavic and the other on the back of the shoulder at the upper bor of the trapezius. Next most frequent were those at the anter axillary border and those in the second and third intercos spaces on the chest. Pressure over the flat surface of the scap also frequently produced pain. A severe degree of sensitiv was observed only in patients with cardiac disorders. Furth more, in these cardiac patients the sensitivity was either entir or predominantly on the left side. There seemed to be a relati ship between the degree of spontaneous pain and degree of se tivity. Those cardiac patients who had severe coronary pain d ing their illness demonstrated the greatest tenderness to pressu In many cardiac patients the tenderness became less as the sp taneous pain diminished during convalescence, but there was significant correlation between the severity of the trigger p and the subsequent course of the cardiac disorder. It is s gested that (1) the trigger areas are the result of focal inflamm tory changes based on reflex vasomotor processes and that fact accounts for their persistence when the visceral source of pain is no longer present; (2) the sensitive areas lie in cl relationship to the larger and more superficial nerves; and the syndrome of referred cardiac pain can best be explained the use of pathways of referral from the visceral autonom source of excitation to other autonomic afferent fibers from shoulder and neck, which enter the same ganglia and the sa cord segments as do the cardiac afferent fibers. Such a conce of referral from autonomic-to-autonomic, rather than autonom to-somatic, would explain many other types of severe deep-lyi pain that do not follow the usual segmental somatic patterns.

Quinoline Therapy in Asthma: Report of 500 Cases. C. Geschickter. South. M. J. 48:497-509 (May) 1955 [Birmingha Ala.].

A series of 500 patients with bronchial asthma was treat with a new quinoline derivative—N, N-diethyl-cis-Δ^4-tetrah drophthalamic acid (Phthalamaquin). It has both bronchodilat and antihistaminic properties, as well as the unusual advanta of localizing in the respiratory tissues. It is administered eithe orally or intramuscularly in 50 mg. doses in the form of its o ganic salt, and intravenously in the form of its ascorbic acid sa in doses of 200 to 500 mg. In long-continued clinical use th safe oral dose is 3 mg. daily per kilogram of body weigh Patients have been treated over periods from 6 to 48 months The results were good to excellent in 80% of the patients, fa in 10%, and poor in the remaining 10%. All of the patients ha previously failed to respond to other treatments.

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1946 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

verse Effects of Therapy in Allergic Disorders. A. Sterling. 11:93-94 (May) 1955 [Kansas City, Mo.].

Many allergic patients who would benefit from desensitization d thus avoid future bronchial asthma and invalidism are lost the medical profession because of overdosing and subsequent nstitutional reactions. Desensitization with potent material ould be undertaken cautiously in highly sensitive persons, with quent minute doses in dilutions as weak as 1:100,000 to 200,000 intradermally. It is best to keep new patients in the ice for 15 to 20 minutes after injections to make sure shock actions do not develop in them. The therapeutic need for inephrine and related compounds varies widely in different rsons. Patients may go through a temporary stage in which y are resistant to the effects of epinephrine, and to continue give the drug in larger and larger doses during this stage can ove extremely harmful to the patient. The antihistamines are luable, especially in the treatment of hay fever because of their ying effect on the respiratory mucosa. In patients with hay er, asthma, and bronchitis, however, interference with expec- ation may cause discomfort. The sedative effect of these drugs st be kept in mind too. The prolonged use of rectal suppos- ries may cause pruritus or proctitis. Corticotropin, cortisone, d hydrocortisone block the allergic process but do not aid in gnosing the cause of the difficulty. Electrolyte metabolism st be checked constantly during therapy with these agents. tassium iodide liquefies bronchial secretion and may relieve ficult expectoration, but it induces marked rhinitis, which may turn aggravate the cough syndrome.

e Low Sodium Syndromes. E. G. Margolin and J. P. Merrill. 11:58-69 (May) 1955 [Kansas City, Mo.].

A low sodium syndrome is produced by one of three mecha- ms: dilution of sodium, i. e., the retention of water over and ove the retention of sodium; depletion of sodium, i. e., an tual decrease in the amount of sodium present in the body, in presence of essentially normal amounts of body water; and listribution of sodium or water in the body (phenomenon of aptation), i. e., the loss of sodium from the extracellular, asurable space or its dilution by water leaving the intracellular ace. Differentiation of these three types of hypotonic state is sed on the following clinical and laboratory data: the patient's rmal weight and recent changes in weight; the presence or sence of edema and dehydration; the recent intake and output fluid; consumption of food; existence of vomiting, diarrhea, d profuse sweating; the presence of visceral disease such as rdiac failure, hepatic insufficiency, renal impairment, or ter- inal cancer; and determinations of serum protein, hemoglobin vel or hematocrit, carbon dioxide combining power, chloride, tassium, serum nonprotein nitrogen, and sodium in the urine d, sometimes, in other body fluids. The best treatment for a tient with hyponatremia due to dilution is restriction of water, companied by general supportive measures. Hyponatremia due sodium depletion is often the direct result of various thera- utic maneuvers. Sodium replacement therapy is usually indi- ted, but it must be accompanied by careful checking of the neral electrolyte balance, particularly against potassium deple- on. Hyponatremia due to redistribution should not be treated administration of excess salt. It is seen postoperatively or the result of chronic stress and is an expression of underlying sease. It may be clinically asymptomatic. Specific instances of w sodium syndromes occur in congestive heart failure, cir- osis with ascites, chronic nephritis, adrenal cortical hypofunc- on (Addison's disease), acute renal insufficiency, the nephrotic ndrome, and in certain cases of central nervous system disease r severe tuberculosis and other cachectic states.

uthyroid Patients with Early Eye Signs of Graves' Disease: heir Response to L-Triiodothyronine and Thyrotropin. S. C. Verner. Am. J. Med. 18:608-612 (April) 1955 [New York].

In a series of 10 patients between the ages of 24 and 63 years with early ocular signs of toxic diffuse goiter consisting of widen- ng of the fissures and a limited degree of proptosis, 7 were euthyroid by every criterion available including basal metabolic rate, fasting cholesterol levels, and chemical serum precipitable iodine values; the other three were euthyroid by all criteria except the serum precipitable iodine, the levels of which were high. After an initial determination of radioactive iodine (I^{131}) uptake at 24 hours by the thyroid made with a 15 μc test dose in the 10 patients, all were given L-triiodothyronine by mouth in doses ranging from 0.07 to 1 mg. daily, for eight days. On the morning of the eighth day the radioactivity in the thyroid was measured, a second 15 μc dose of I^{131} was administered and the 24 hour uptake again determined. The absence of decrease in uptake by the thyroid in these euthyroid patients with ocular signs of toxic diffuse goiter was striking in contrast to the marked decrease in uptake shown by 30 euthyroid control persons. Thyrotropin was administered intramuscularly to eight patients in doses of 10 units (30 mg.) daily for three days. A diagnostic dose of 15 μc of I^{131} was given orally on the third day, and the uptake was determined 24 hours later. Although there was a slight increase in average uptake of I^{131} by the thyroid, the amount was negligible in five of the eight patients tested. A brisk increase in the serum precipitable iodine level followed thyrotropin administration in all patients. The author's patients responded to triiodothyronine and thyrotropin like patients with overt toxic diffuse goiter. It is concluded that these patients did, in fact, have toxic diffuse goiter. It is demonstrated that the normal pituitary-thyroid relation is disrupted in these patients and that euthyroidism can be maintained despite this disruption. The disruption of the normal relations and the abnormal responses of these patients to thyrotropin may be considered as further evidence that toxic diffuse goiter is not caused by hyperpituitarism but is mediated by mechanisms apart from that gland. Triiodothyronine and the 24 hour uptake method provide a new and highly reliable test of thyroid function.

Significance of Lowering of Vitamin E Concentration in Serum of Patients with Liver Diseases. A. Bäumer and R. Beckmann. Klin. Wchnschr. 33:431-434 (May 1) 1955 (In German) [Berlin, Germany].

The concentration of vitamin E in the serum was determined in 54 patients, 15 of whom had epidemic hepatitis, 8 cirrhosis of the liver, 5 obstructive jaundice, 11 so-called intermittent juvenile jaundice of Meulengracht type, one subacute atrophy of the liver, 2 primary carcinoma of the liver, and 8 carcinoma of various organs not associated with icterus. Results showed that diseases of the liver and jaundice of Meulengracht type are almost always associated with a disturbance of vitamin E metabolism. As a rule this disturbance is manifested by a lowering of the concentration of vitamin E in the serum. A marked increase in the concentration of vitamin E in the serum of one of the patients with carcinoma of the liver not associated with jaundice could not be explained. To study the influence of vitamin E on the function of the adrenal cortex, three patients with cirrhosis of the liver, two with hepatitis, one with cholangitis, and four with jaundice of Meulengracht type were treated with alpha-tocopherol. Concentration of vitamin E in the serum and total-neutral-C-17-ketosteroid excretion in the urine were determined in these patients before and after treatment with alpha-tocopherol. An increase in the total-neutral-C-17-ketosteroid excretion in the urine was observed in all 10 patients. It was associated with increase in concentration of alpha-tocopherol in the serum of these patients and with definite improvement of their subjective general complaints. Vitamin E did not exert any influence on the changes of the metabolism of the biliary pigment and the serum protein structure in the patients with diseases of the liver, and it did not have any effect on the hyperbilirubinemia of the patients with icterus of Meulengracht type.

Clinical Evaluation Studies in Lepromatous Leprosy: First Series: Diasone (Diamidin), 4-4'-Diaminodiphenyl Sulfone, Dihydrostreptomycin. J. A. Doull. Internat. J. Leprosy 22:377-402 (Oct.-Dec.) 1954 [New Orleans].

A series of patients with lepromatous leprosy were selected and assigned in equal numbers to six therapy groups by a method that gave priority to comparability in sex and age and took into account other characteristics relevant to prognosis. These groups were subjected to impartial appraisal after 32 to 48 weeks. The drugs and combinations used were: (1) diasone (diamidin), (2) 4-4′-diaminodiphenyl sulfone (DDS), (3) dihydrostreptomycin sulfate, (4) diasone plus dihydrostreptomycin sulfate, (5) dihydrostreptomycin sulfate plus sodium *p*-aminosalicylate and (6) a placebo or sodium *p*-aminosalicylate alone. Therapy and examinations were completed in 852 patients. Diasone, DDS, and dihydrostreptomycin proved of definite and about equal value in the treatment of lepromatous leprosy. A combination of dihydrostreptomycin and diasone showed no advantage over either given singly, and addition of sodium *p*-aminosalicylate to dihydrostreptomycin did not augment its effectiveness. The proportion of patients who, on clinical grounds, were considered to be moderately or markedly improved was 20% after 32 weeks, and 25 to 30% after 48 weeks. Very few of the patients who were given placebos improved, but about 17% of the controls given sodium *p*-aminosalicylate showed improvement, which suggests that this drug may have some beneficial effect.

Type E Botulism Due to Salmon Eggs. C. E. Dolman, G. E. Darby and R. F. Lane. Canad. J. Pub. Health 46:135-141 (April) 1955 [Toronto, Canada].

In November, 1954, three young Indian women (sisters) in British Columbia fell ill with symptoms suggesting botulism. The incriminated foodstuff was salmon egg cheese, made by a tribal method that involves washing and smoking the mass of eggs, which are then allowed to mature in boxes or tins for two to four weeks before consumption. The sisters ate the salmon egg cheese raw, and one of them died. A strain of Clostridium botulinum type E was isolated from her stomach contents, and also from samples of the salmon eggs consumed. Its toxigenic capacity in laboratory mediums resembled that of other type E strains, cultures attaining a potency of 1,000 to 3,000 mouse minimum lethal dose per milliliter. The circumstances of this outbreak of botulism permitted the lethal dose of type E toxin for man to be fairly accurately determined at around 500,000 mouse minimum lethal dose. In the period 1944 to 1954 there have been four outbreaks of type E botulism in British Columbia, all due to uncooked or insufficiently cooked fish or fish products. Of the nine persons affected, six died.

Recognition of Abnormal Hemoglobin Syndromes. R. H. Alway. Journal-Lancet 75:215-222 (May) 1955 [Minneapolis].

Filter-paper electrophoresis provides a relatively simple and inexpensive means of determining the electrophoretic mobilities of hemoglobins A (adult), S (sickling), C, and F (Fetal). Hemoglobins D and F may be recognized by further studies. Although sickling is most easily recognized in patients with sickle-cell anemia and sickle-cell thalassemic disease, it is also found in those with sickle trait, sickle-cell hemoglobin C disease, and sickle-cell hemoglobin D disease. Leptocytosis suggests the presence of hemoglobin C. It is most marked in homozygous hemoglobin C disease but is also seen to a lesser extent in sickle-cell hemoglobin C disease, sickle-cell anemia, hemoglobin C trait, and in thalassemia major and minor. Erythrocyte hypochromia and microcytosis may be noted in the thalassemic conditions. Splenomegaly is most marked in thalassemia major. It is progressive in sickle-cell thalassemic disease and sickle-cell hemoglobin C disease but usually regresses before adolescence in sickle-cell anemia. It is less marked in homozygous hemoglobin C disease and thalassemia minor. Arthralgia is noted not only in the three most common forms of sickle-cell disease, i. e., sickle-cell anemia, sickle-cell hemoglobin C disease, and sickle-cell thalassemic disease, but also in persons homozygous for hemoglobin C. Hematuria is of possible significance in sickle-cell hemoglobin C disease.

Treatment of Acute Leukemia with Fluorohydrocortisone. J. M. Hill and L. Vincent. Sang 26:269-281 (No. 3) 1955 (In French) [Paris, France].

Seventeen patients with acute leukemia of various types were treated with 9-α fluorohydrocortisone acetate. Daily massive doses theoretically equivalent to 5 or 10 gm. of hydrocortisone were used without serious side-effects. Seven complete remissions were obtained, three partial remissions, and four fai in the 14 patients who received a total of more than 250 of the drug. Three other patients were admitted to hospita the terminal stages of their disease. The action of the drug, w successful, was unusually prompt. One of the complete re sions occurred in a patient with plasmocytic leukemia. Of 10 patients with remissions, 5 had never been treated a received no other antileukemic chemotherapy during flu hydrocortisone therapy. The drug appears capable of produ remissions in patients in whom other agents, including cor tropin administered intravenously, are no longer useful. remissions obtained do not last any longer than those from c types of hormone therapy. Marrow examinations in this s showed an increase in the fragility and destruction of the kemic cells and some mitotic anomalies. It is not known wh these phenomena represent a quantitative or qualitative d ence of fluorohydrocortisone relative to the action of corti and hydrocortisone. In almost every patient there was de stimulation of erythropoiesis with frequent passage of nucle blood cells into the peripheral blood varying in general bet 5 and 15% white elements. The platelets were not so const affected.

Nonsuppurative Intrathoracic Complications of Ameb R. Coirault, H. Coudreau and J. Girard. Semaine hôp. Pari 1591-1602 (May 6) 1955 (In French) [Paris, France].

Difficult problems often arise in connection with the d ential diagnosis of the intrathoracic manifestations of ameb which may consist not only of a primary amebic abscess i lung, without any concomitant involvement of the liver, an abscess localized at the base of the right lung, represe an extension into the thorax of an abscess in the liver, but of various suppurative and nonsuppurative pleuropulm complications. Patients with nonsuppurative intrathoracic festations present three major syndromes: (1) diffuse pleur monary involvement of the base of the right lung; (2) p chymatous foci, either pneumonic or in the form of dissemi infiltrates; and (3) serofibrinous pleural effusions. Amebic titis was invariably found in the authors' patients, and its tion, though often difficult, is an essential part of the diag because it proves the amebic origin of the pleuropulmonary drome. Many of the signs and symptoms presented by the pa are subject to misinterpretation. They are often attributed t mary pulmonary disease and as a result the underlying hepat overlooked. Failure to identify and treat the hepatitis, how may be followed by abscess formation with the danger of s suppurative complications in the thorax unless the absces be drained either medically or surgically. A trial treatment emetine, which is remarkably effective in amebic conditions, establish the diagnosis in doubtful cases. Patients with no purative intrathoracic complications of amebic origin us recover rapidly when treated with emetine. The fever subs the sedimentation rate returns to normal, and the general c tion improves. The clearing of the radiological findings, how may take longer than the resolution of the hepatitis. Atte should always be given to persistence of the radiological in evaluating a cure, because the relief of the hepatitis ma only temporary, and its reactivation may result in further i thoracic complications.

Suppurative Intrathoracic Manifestations of Amebiasis. R. ault, H. Coudreau and J. Girard. Semaine hôp. Paris 31:1 1617 (May 6) 1955 (In French) [Paris, France].

The suppurative intrathoracic manifestations of amebiasis into two groups: (1) syndromes of pulmonary suppuration purulent vomica and (2) various forms of empyema. Reco with complete return to health of the pulmonary parench takes place in almost all patients, but more or less signifi pleural sequelae are left. The suppurative manifestations of a biasis are seldom primary, almost always appearing as compl tions of amebic hepatitis, which may or may not be evid The elements that establish amebiasis as the cause of the co tion are the presence of hepatitis; the macroscopic character the pus and its abundance and sterility (except in cases of seco y infection); and the spectacular improvement rapidly obtained treatment with emetine alone. The purulent matter found in e thorax in about 80% of these patients comes from a liver scess that has ruptured and perforated the diaphragm. Only e difficulties encountered in obtaining an accurate diagnosis such an abscess can excuse the occurrence of this complicaon. Failure to diagnose and treat the hepatitis, either because e patient did not seek advice promptly or because it was asked by pleuritic or pneumonic symptoms, may result in the rmation of a hepatobronchial fistula and massive vomiting of s, differing in character according to the age of the abscess. is phase of the disorder, which rarely lasts more than three ys, is followed by regression of the hepatitis and an immediate mission of the clinical signs. Treatment with emetine will comete the cure. Most amebic abscesses of the lung can be traced pus from a ruptured liver abscess, but in some patients intralmonary suppuration is apparently caused by amebas that ve been transported to the lungs either by the blood or the mph. Empyema, which is the most serious intrathoracic manistation of amebiasis, may appear abruptly, causing severe pain d shock in a patient whose general condition has been imired by a latent hepatic abscess. Treatment for shock and ompt evacuation of the purulent matter by puncture aspiration, mbined with antibiotics and antiamebic medications, will usuly cure both the hepatic abscess and the empyema, although covery may be delayed by complications such as bronchopleural tulas and pleurisy. Empyema that is insidious in its onset may pear as a severe purulent pleurisy, or it may become encysted the base of the right lung. Amebic empyema in all its forms ually yields to medical treatment, but it may be fatal, and even hen it can be cured it has important sequelae, because the resultg retraction of the thorax and virtual immobilization of the diaragm reduce the functional capacity of the lung.

igestive Ailments of Older Patients. A. M. Snell. Minnesota ed. 38:309-314 and 330 (May) 1955 [St. Paul].

Many of the gastrointestinal complaints in the aged are caused curable or correctable lesions. Acute or reactivated peptic cer is relatively common in patients over 60 years of age, and th the incidence and gravity of hemorrhage appear to increase ith age. Obstruction is noted in 10 to 15% of old patients with ptic ulcer. Gallstones are probably the commonest single use of severe abdominal pain in patients over 65 years of age d neither the location nor the exact character of the pain is much diagnostic value. As a rule the old patient with gallones tolerates operation well and there are few contraindicaons. The major problem referable to the colon in old patients constipation. The patient should be persuaded that the intesne need not be emptied every day and that no physical harm ill result from an overdue stool. Diarrhea in old people is oublesome; occasionally it is associated with achlorhydria d probably also with deficient intestinal absorptive capacity. his may be relieved in part by parenteral administration of ver extract and the use of vitamin concentrates. Although mplications of cirrhosis of the liver, chiefly hemorrhages from arices and episodes of hepatic necrosis, are often fatal in old ersons, some of the older cirrhotic patients may survive for ears in a fair state of health. In many of the patients of adanced age, the complaints, however bizarre and atypical, are kely to have an organic background. The diagnosis of the rganic disease is often far from easy, chiefly because the usual lues that lead to diagnosis are absent or distorted. If the symptoms are of brief duration, full investigation is compulsory. If hey are a continuation of those that have plagued the patient ll his life, investigation is still essential, if only to provide the ecessary reassurance and support essential to treatment. Sympomatic treatment without full investigation is risky at best, nd temporizing on such a basis is the cause of much disability nd many fatalities in the aged. It should not be forgotten that ersons who reach the eighth decade of life are of a rather pecial pattern and not infrequently are made of better biological materials than their juniors. Their tolerance of operations may be amazingly good and their recovery from even major procedures rapid. Here is a field in which all physicians can participate in reducing mortality and morbidity rates and in making life more bearable for many persons who have passed their prime.

An Outline of the Newer Methods of Study of Atherosclerosis with Emphasis on the 80 to 100 Year Group. H. B. Eiber, A. A. Goldbloom, O. Deutschberger and others. Geriatrics **10**:213-220 (May) 1955 [Minneapolis].
